# OXIDE CHEMISTRY AND THERMODYNAMICS OF MOLTEN <br> LITHIUM FLUORIDE-BERYLLIUM FLUORIDE BY EQUILIBRATION WITH GASEOUS WATER-HYDROGEN FLUCRIDE MIXTURES 

A. L. Mathews*
C. F. Baes, Jr.
*Present address: Western Carolina College, Cullowhee, North Carolina.

A dissertation submitted to the Faculty of The University of Mississippi in partial fulfillment of the requirements for the Degree of Doctor of Philosophy in the Department of Chemistry.
LEGAL NOTICE -_
This report was prepared as an account of Government sponsored work. Neither the United States,
nor the Commission, nor any person acting on behalf of the Commission:
A. Makes ony warranty or representation, expressed or implied, with respect to the accuracy,
completeness, or usefulness of the information contained in this report, or that the use of
any information, apparatus, method, or process disclosed in this report may not infringe
privately owned rights; or
B. Assumes any liabilities with respect to the use of, or for damages resulting from the use of
any information, apparatus, gethod, or process disclosed in this report.
As used in the above, "person acting on behalf of the Commission" includes any omployee or
contractor of the Commission, or employee of such contractor, to the extent that such employee
or contractor of the Commission, or employee of such contractor prepares, disseminates, or
provides access to, any information pursuant to his employment or contract with the Commission,
or his employment with such contractor.

This report is based upon a dissertation submitted to the University of Mississippi in partial fulfillment of the requirements for the doctoral degree. The report describes research carried out in the Reactor Chemistry Division of the Oak Ridge National Laboratory, which is operated by the Union Carbide Corporation for the Atomic Energy Commission. The research was supported by the Oak Ridge Graduate Fellowship Program of the Oak Ridge Institute of Nuclear Studies and was directed by a committee appointed by Dean Lewis Nobles of the University of Mississippi Graduate School which was composed of Dr. George Vaughan and Dr. Allen Cahill of the Department of Chemistry at the University of Mississippi and Dr. C. F. Baes, Jr., and Dr. C. H. Secoy of the Reactor Chemistry Division of the Oak Ridge National Laboratory.

IITHIUM FLUORIDE-BERYITTUM FLUORIDE BY EQUIIIBRATION WITH GASEOUS WATER-HYDROGEN FLUORIDE MIXTIURES

A. I. Mathews<br>C. F. Baes, Jr.

#### Abstract

The transpiration method was used to equilibrate dilute gaseous mixtures of HF and $\mathrm{H}_{2} \mathrm{O}$ in hydrogen carrier gas with molten LiF-BeF2 mixtures varying in composition from 0.25 to 0.80 BeF 2 , both saturated and unsaturated with crystalline BeO , in the temperature range 500 to $700^{\circ} \mathrm{C}$. The partial pressure data were used to evaluate the equilibrium quotient for the reaction of HF and $\mathrm{H}_{2} \mathrm{O}$ with solid BeO and dissolved $\mathrm{BeF}_{2}$. Equilibrium quotients were also obtained for the formation of oxide and hydroxide ions in the liquid phase.

These equilibrium quotients were employed to determine: (1) thermodynamic activities of LiF and $\mathrm{BeF}_{2}$ in the mixtures; (2) thermodynamics of liquid $\mathrm{BeF}_{2}$; (3) stability of hydroxide in the melt; and (4) solubility of BeO in the LiF-BeF2 system as a function of temperature.

## I. INTRODUCTION

Molten mixtures of LiF and BeF2 have been the subject of numerous investigations in recent years primarily because of their suitability as a carrier solvent for UF4 in fluid fueled nuclear reactors. In addition, these solutions are especially worthy of study because the components highly ionic $\operatorname{LiF}$ and highly associated, more covalent BeF2 - represent extreme types of fluoride salts. Although the molten LiF-BeF2 system has received considerable attention from both a practical and a theoretical point of view, the study of its chemistry is still far from complete. According to Everest, ${ }^{1}$ many of the investigations of beryllium fluoride systems did not take into account the role of moisture and the resulting hydrolysis products. If this information were available, future investigators could make appropriate experimental adjustments and corrections.

The purpose of the present investigation was to study heterogeneous reactions of the type
$\mathrm{H}_{2} \mathrm{O}(\mathrm{g})+$ fluoride $\operatorname{species}(\mathrm{soln}) \rightleftharpoons \mathrm{HF}(\mathrm{g})+$ oxygen species $($ soln $)$
in the molten LiF-BeF2 system. From such a study information could in principle be obtained about: (1) the thermodynamic activities of LiF and $\mathrm{BeF}_{2}$, (2) the solubilities and stabilities of oxides, and (3) the interaction of oxide with the proton and perhaps other cations in this molten fluoride system. Information about the chemical reactivity of the components in the molten LiF-BeF2 system could be obtained from the thermodynamic activities of LiF and BeF2. The oxide chemistry of this system is of interest because oxide is a principal impurity to be dealt with in preparative work and because metal oxides are known to be only sparingly soluble in LiF-BeF2 mixtures.

The presence of oxide species in the molten $\mathrm{LiF}-\mathrm{BeF}_{2}$ system, which is currently being used as the solvent in the Molten-Salt Reactor Experiment at $O R N L$, constitutes an undesirable impurity since inadvertent precipitation of sparingly soluble uranium (and other) oxides might result in unstable reactor operation. One of the steps in the purification of melts for reactor operation is sparging with a mixture of HF and $\mathrm{H}_{2}$ to remove oxide. The present study of the equilibria involved would yield additional guidelines for this treatment.

The reactivity of oxide with beryllium and other cations has been investigated as a possible means of removal of reactor products, or of uranium to be reprocessed for later use. In order for proper evaluation of these methods to be carried out, a thorough understanding of the interactions occurring in melts would be desirable. For example, the use of
$\mathrm{H}_{2} \mathrm{O}$ as the source of reactive oxygen for oxide precipitating schemes and the use of $H F$ for removal of oxide require that the stability of the intermediate hydroxide be evaluated in the melts.

In the present study the transpiration method was used to equilibrate dilute gaseous mixtures of HF and $\mathrm{H}_{2} \mathrm{O}$ in hydrogen carrier gas with molten LiF-BeF2 mixtures varying in composition from 0.25 to $0.80 \mathrm{BeF}_{2}$, both saturated and unsaturated with crystalline BeO , in the temperature range 500 to $700^{\circ} \mathrm{C}$. The primary data from the measurements were used to evaluate the equilibrium quotient for the reaction of HF and $\mathrm{H}_{2} \mathrm{O}$ with solid BeO and dissolved $\mathrm{BeF}_{2}$. Equilibrium quotients were also obtained for the formation of oxide and hydroxide ions in the liquid phase. These quantities in turn could be used to obtain the thermodynamic activities of LiF and $\mathrm{BeF}_{2}$ as well as the solubility of BeO and the stability of hydroxide. Use of the $\mathrm{HF}-\mathrm{H}_{2} \mathrm{O}$ equilibria as a much needed analytical tool for the determination of oxide in such melts was also indicated.

## Physical Properties of the $\mathrm{LiF}-\mathrm{BeF}_{2}$ System

Beryllium fluoride is frequently found in the form of a glass rather than a crystalline solid. The beryllium fluoride glass consists of a random network structure in which the beryllium atoms are surrounded tetrahedrally by four fluorine atoms and each fluorine atom by two beryllium atoms. ${ }^{1}$ Liquid beryllium fluoride retains the polymeric character of the glass as indicated by its high viscosity. In contrast to the covalent nature of beryllium fluoride, lithium fluoride is a highly ionic salt. The addition of LiF to liquid $\mathrm{BeF}_{2}$ causes a breaking down of the polymeric structure, but apparently the tetrahedral $\mathrm{BeF}_{4}{ }^{2-}$ groups are retained.

Although it isn't proof of structure in the liquid phase, the fact that a compound $\mathrm{Li}_{2} \mathrm{BeF}_{4}$ can be precipitated from the melt may be some indication of the short range order in the liquid phase.

Phase behavior of the LiF-BeF2 system has been studied extensively by Thoma, et al. ${ }^{2}$ A copy of their published diagram (Figure 1) is included here to illustrate the major characteristics of the system.

The melting point of $\mathrm{BeF}_{2}$ is $548^{\circ} \mathrm{C}$; the melting point of LiF is $848^{\circ} \mathrm{C}$. The liquidus temperatures for the $\mathrm{BeF}_{2}-\mathrm{rich}$ region have been difficult to obtain because of the high viscosity of these solutions. ${ }^{3}$ A brief summary of the phase studies of various $\mathrm{BeF}_{2}$ systems is included in reference 1 . Many of these systems parallel those of the much higher melting silicate glasses.

Studies of the LiF-BeF2 system in the temperature range of the present work ( 500 to $700^{\circ} \mathrm{C}$ ) are restricted to the region between the high liquidus temperatures at low $\mathrm{BeF}_{2}$ concentrations and high viscosity at high $\mathrm{BeF}_{2}$ concentrations.

Fig. 1. Phase Diagram of the LiF-BeF2 System (From Thoma, ref. 2).

Thermodynamic Properties of the Various Possible Species

From previous studies of $\mathrm{LiF}, \mathrm{BeF}_{2}$, and the other possible species present, some information can be drawn about the expected behavior of the system. The thermochemical data for $\mathrm{BeF}_{2}$ are summarized in the JANAF Tables. ${ }^{4}$ There is considerable uncertainty in $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}$ of $\mathrm{BeF}_{2}(1)$, which was derived from the $\Delta H_{f}{ }^{\circ} 298.15$ for the crystal and the appropriate heat capacity functions for both the solid and liquid phases. Two sources of error were cited in JANAF. The heat capacity studies were made on samples of $\mathrm{BeF}_{2}$ which contained BeO and $\mathrm{H}_{2} \mathrm{O}$. Also, the heat of fusion is uncertain. The value of $2 \mathrm{kcal} /$ mole was used in the tabulation (because of the similarity of BeF 2 glass to $\mathrm{B}_{2} \mathrm{O}_{3}$ and $\mathrm{SiO}_{2}$ ) even though a value of $12.9 \mathrm{kcal} / \mathrm{mole}$ was determined from the vapor pressures over solid and liquid $\mathrm{BeF}_{2}$. Determination of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}$ of $\mathrm{BeF}_{2}(\underline{1})$ would help resolve some of these difficulties.

The thermochemical properties of $\mathrm{BeF}_{2}(\mathrm{~g})$ have been based on properties of the liquid and the heat of vaporization of $\mathrm{BeF}_{2}(\underline{1})$ except for the work of Greenbaum, et al. ${ }^{5}$ who determined equilibrium constants for the reaction
$\mathrm{BeO}(\mathrm{s})+2 \mathrm{HF}(\mathrm{g}) \rightleftharpoons \mathrm{BeF}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$
over the temperature range 670 to $970^{\circ} \mathrm{C}$. They report that a plot of log K vs $1 / T$ yields a least squares slope corresponding to $20.5 \pm 1.7 \mathrm{kcal} / \mathrm{mole}$ for $\Delta H_{r}$ over the temperature range studied, and that a plot of $\Delta F_{r}$ vs $T$ gives a value of $6.0 \pm 0.3 \mathrm{cal} \mathrm{deg}^{-1} \mathrm{~mole}^{-1}$ for $\Delta S_{r}$ by a least squares analysis. If the calculated line for $\log \mathrm{K}$ vs $1 / T$ using these parameters were drawn and the reported equilibrium quotients plotted, the line would fall on the same side of all points. A least squares analysis using all
published data, with equal weighting for all points, gave values of $\Delta H_{r}=$ $20.28 \pm 0.84 \mathrm{kcal} / \mathrm{mole}$ and $\Delta S_{r}=6.67 \pm 0.77 \mathrm{cal} \mathrm{deg}{ }^{-1} \mathrm{~mol}^{-1}$. From their values Greenbaum, et al. ${ }^{5}$ reported the $\Delta H_{f}{ }^{0} 298$ of $\mathrm{BeF}_{2}(\mathrm{~g})$ as -191.3 $\pm$ $2.0 \mathrm{kcal} / \mathrm{mole}$ and $\mathrm{S}_{298}^{0}$ of $\mathrm{BeF}_{2}(\mathrm{~g})$ as $52.4 \pm 0.3{\mathrm{cal} \mathrm{deg}^{-1} \mathrm{~mole}}^{-1}$. Based on the recalculation, the values would be $-191.5 \pm 1.1$ and $53.1 \pm 0.8$, respectively.

The vapor pressure of $\mathrm{BeF}_{2}(1)$ has been studied extensively. $6-10$ Sense, et al. ${ }^{6,7}$ studied the vapor pressure from 745 to $1021^{\circ} \mathrm{C}$. Two Russian groups 8,9 have reported vapor pressure studies. All oif these are in general agreement but have slight differences. The most extensive, and probably the best, study ( 550 to $950^{\circ} \mathrm{C}$ ) was that of Greenbaum, et al. ${ }^{10}$ since the enthalpy and entropy of vaporization are reasonably well known from these measurements, a combination of this information with independently determined entropy and enthalpy of formation of $\mathrm{BeF}_{2}(\underline{1})$ should provide a new means for evaluating the thermodynamic properties of $\mathrm{BeF}_{2}(\mathrm{~g})$.

The thermodynamic values of $\mathrm{H}_{2} \mathrm{O}(\mathrm{g}), \mathrm{HF}(\mathrm{g})$, and $\mathrm{BeO}(\mathrm{s})$ are well characterized throughout the temperature range of the present measurements (see reference 4). Thus, if the $\Delta H_{r}$ can be determined for the reaction $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})+\mathrm{BeF}_{2}(\underline{\mathrm{I}}) \rightleftharpoons 2 \mathrm{HF}(\mathrm{g})+\mathrm{BeO}(\mathrm{s})$, then $\Delta H_{f}{ }^{\circ}$ of $\mathrm{BeF}_{2}(\underline{I})$ can be calculated. The greatest uncertainty in $\Delta H_{f}{ }^{\circ}$ for $H F(g)$ is the correction which should be applied for the imperfection at room temperature. Several recent publications have dealt with the subject. ${ }^{11-15}$ Franck and Spalthoff ${ }^{11}$ reported that the enthalpy of vaporization rises from $89.5 \mathrm{cal} / \mathrm{g}$ at $19.4^{\circ} \mathrm{C}$ to a $\max$ of $146 \mathrm{cal} / \mathrm{g}$ at $130^{\circ} \mathrm{C}$ and decreases at higher temperature. Armitage, et $\frac{a l}{} .{ }^{12}$ show that the various thermodynamic properties can best be explained by assuming that HF exists
in the gas phase principally as monomers and hexamers, but no actual indication of the average molecular weight as a function of temperature or pressure is given. Yabroff, et $\mathrm{al} .{ }^{13}$ have summarized most past work in their report. They conclude that HF molecules are strongly associated into polymeric forms and that dissociation is accompanied by large changes in enthalpy. Armstrong ${ }^{14}$ and Feder, et al. ${ }^{15}$ have considered the effect of this association on the heat of formation of $\mathrm{HF}(\mathrm{g})$. The average molecular weight of $\mathrm{HF}(\mathrm{g})$ at 1 atm and $25^{\circ} \mathrm{C}$ is 54 , at 0.4 atm and $25^{\circ} \mathrm{C}$ is 22 , and at 1 atm and $80^{\circ} \mathrm{C}$ is $20 .{ }^{16}$ For pressures as low as a few hundredths of an atmosphere both HF and $\mathrm{H}_{2} \mathrm{O}$ are reasonably ideal at $25^{\circ} \mathrm{C}$ and undoubtedly are ideal at melt temperatures.

From the thermodynamic quantities tabulated in JANAF, equilibrium constants were calculated for several conceivable reactions involving HF , $\mathrm{H}_{2} \mathrm{O}, \mathrm{BeF}_{2}, \mathrm{BeO}$, and LiF. These are presented in Table 1 along with the

calculated heats of reaction. Although the equilibrium constants refer to reactants and products which are pure solids or liquids, they could be applied to reactions in solution if appropriate activities were used. From these data the following predictions are made:
(1) Oxygen containing compounds of $L i$ should react to form Be compounds. If $\mathrm{Li}_{2} \mathrm{O}$ were added to an $\mathrm{IiF}-\mathrm{BeF}_{2}$ melt, the $\mathrm{Li}_{2} \mathrm{O}$ should react almost quantitatively to form BeO and LiF. If LiOH were added to an LiF-BeF2 melt, the LiOH should react almost quantitatively to form $\mathrm{Be}(\mathrm{OH})_{2}$ and LiF.
(2) The formation of $\mathrm{Be}(\mathrm{OH})_{2}$ as a separate solid phase at temperatures as high as $800^{\circ} \mathrm{K}$ is very unlikely.
(3) All of the stable compounds have low volatilities at the temperatures of interest.

A more precise determination of the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}$ of $\mathrm{BeF}_{2}(\underline{I})$ and of the activities of $\mathrm{BeF}_{2}$ and LiF in the melt would allow more quantitative predictions of reactions in the $\mathrm{LiF}-\mathrm{BeF}_{2}$ system.

Thermodynamic Studies of Molten Salt Mixtures

The determination of thermodynamic activities of melt components in molten salts has received considerable attention. Blander has summarized much of the work through $1962 .{ }^{17}$

The relationships between activities and activity coefficients depend on the choice of concentration units. The most frequent unit for expressing concentration of mixed solvents is the mole fraction. In molten salts the ion fraction is frequently used. For systems in which all salts contain the same anion, mole fraction and ion fraction are equal. The term "mole fraction" will be used in the text.

According to the Temkin model, ${ }^{18}$ in which salts are considered to be completely ionic, the ideal activity of a component is equal to the product of ion fractions of its constituents $\left(a_{i j}=X_{i} X_{j}\right)$. For a solution which contains only one anion, $j$, the ion fraction, $X_{j}$, equals one. The ion fraction of each cation is equal to the mole fraction of that component. The activities of components are usually referred to the pure liquid (supercooled if necessary) as the standard state. Occasionally, the activities are referred to the pure crystalline solid for experimental convenience.

The activities of components in solution have been measured by the following methods: vapor pressures, freezing point depression, electrode potentials, and heterogeneous equilibria. The vapor pressure method is complicated by the formation of complex species in the vapor phase. Determination of activities from freezing point depressions requires that the heat of fusion and the $\Delta C_{p}$ for the pure solid and liquid solvent be known. Electrode potential measurements of activities are often made in cells with liquid junction. Such measurements are limited to dilute solutions, which are expected to give small liquid junction potentials.

The use of heterogeneous equilibria has thus far been limited. The activity of $\mathrm{MgCl}_{2}$ has been determined ${ }^{19,20}$ in mixtures with KCl and NaCl by use of the equilibrium
$\mathrm{MgCl}_{2}(\mathrm{soln})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons \mathrm{MgO}(\mathrm{s})+\mathrm{Cl}_{2}(\mathrm{~g})$.
Blood, et al. ${ }^{21}$ determined the activities of various metal fluorides in LiF-BeF2 mixtures using the equilibrium
$\mathrm{M}(\mathrm{s})+\mathrm{xHF}(\mathrm{g}) \rightleftharpoons \mathrm{MF}_{\mathrm{x}}(\mathrm{soln})+(\mathrm{x} / 2) \mathrm{H}_{2}(\mathrm{~g}) \cdot$
In studies of this type it is important that the solid present be well characterized and relatively insoluble and, of course, that all phases are in equilibrium.

If the activity of one of the components of a binary mixture is known as a function of composition, the other one can be determined by integration of the Gibbs-Duhem equation. From the activities, such properties as molar heats of mixing, excess chemical potential, vapor pressure, and phase behavior can be derived.

At present, a general theory of the behavior of melts has not been developed to the point that activities can be predicted for a system such as LiF-BeFz.

The activities of LiF and $\mathrm{BeF}_{2}$ have been reported for a limited number of cases. Berkowitz and Chupka in 1960 reported the activities in an equimolar mixture from relative ion intensities during mass-spectral analysis. ${ }^{22}$ Recently, Büchler has reported determinations by a more careful mass-spectral analysis and emf measurements. The emf measurements were conducted at two temperatures in a concentration cell containing pure BeF2 in one compartment and an LiF-BeF2 mixture in the other. ${ }^{23}$ Buchler used a twin crucible assembly in his determination of activities with the mass spectrometer to facilitate comparison of pure compound and mixture. ${ }^{24}$ The results of these experiments are conmiled in Table 2.

Table 2. Activities of $\mathrm{I} i \mathrm{~F}$ and BeF2 from Literature

## Solubilities of Gases in Melts

In addition to the studies of activities in melts, the solubilities of gases have also been of interest. Watson, et al. ${ }^{25}$ have studied the solubility of the inert gases in molten fluorides, including the LiF-BeF2 system. All solubilities obey Henry's law and increase with increasing temperature and with decreasing atomic weight of gas.

Burkhard and Corbett ${ }^{26}$ reported the solubility of water in molten LiCl-KCl mixtures. Apparently Henry's law was obeyed for low pressures, with the deviations above a few millimeters attributed to hydrolysis. However, no analyses were reported on the gases to determine the amount of $\mathrm{H}_{2} \mathrm{O}$ and HCl in the gas phase in equilibrium with the melt.

Shaffer, et al. ${ }^{27,28}$ have studied the solubility of $H F$ in molten fluoride mixtures. In the $\mathrm{LiF}-\mathrm{BeF}_{2}$ system ${ }^{28}$ solubility of HF increases with
decreasing temperature and with decreasing $\mathrm{BeF}_{2}$ concentration. The Henry's law constants indicate that the solubility of HF in the $\mathrm{IiF}-\mathrm{BeF}_{2}$ system should be less than 150 ppm per atm HF above the melt. Thus, for the present studies with partial pressures less than 0.02 atm HF , the solubility should be less than 3 ppm .

## Determination of Oxides in Melts

Since the presence of oxide in molten halides affects many physical and chemical properties, quantitative procedures for determination of the amount of oxide present have been widely sought. Goldberg, et al. ${ }^{29}$ proposed high-temperature fluorination with KBrF 4 with liberated $\mathrm{O}_{2}$ measured tensimetrically. This method works reasonably well, but the greatest uncertainties were found with fluoride melts and with samples containing less than 300 ppm .

Porter and Brown ${ }^{30}$ used an inert-gas fusion technique (described by Banks, et al. ${ }^{31}$ ) in determining oxide concentrations in molten fluorides. Samples of the melt were withdrawn through graphite filters and the entire sample was used in the analysis. The reported analyses indicated the relative precision was $\pm 10 \%$ for oxide concentrations of about $0.5 \%$. No indication was made of applicability to lower concentrations.

Delarue ${ }^{32,33}$ has determined relative oxide solubilities in LiCl-KCl melts electrochemically. The concentration of oxide was determined in the melt with $\mathrm{Pt}-\mathrm{C}$ electrodes vs a $\mathrm{Pt}-\mathrm{PtCl}_{2}$ reference electrode. These results permitted identification of a variety of reactions involving oxide.

None of the methods cited are adequate for determining oxide in the LiF-BeF2 system. From studies of oxide solubility by Baes, et al. ${ }^{34}$ in
which weighed samples of BeO were added to fluoride melts containing uranium and zirconium, it was estimated that the solubility of BeO was less than 1000 ppm . Determination of oxide content in filtered samples by the Goldberg method, 29 however, gave very inconclusive results.

## Suitable Experimental Approach

The molten salt production facility at the Oak Ridge Y-12 Plant has made use of HF-sparging to remove oxide from solution in the form of water. 35 Since the production procedure parallels the transpiration method for determining vapor pressures of liquids, the feasibility of transpiration techniques for an equilibrium study of the $\mathrm{LiF}-\mathrm{BeF} 2$ system was considered. Much of the feasibility study was conducted by M. K. Kemp who determined partial pressures over the $\mathrm{ZrO}_{2}-$ saturated $\mathrm{LiF}-\mathrm{BeF}_{2}-\mathrm{ZrF}_{4}$ system and was able to estimate the activity of $\mathrm{ZrF}_{4}$ in solution. ${ }^{36}$

Transpiration Method
The transpiration method for determining vapor pressures of liquids is well established. 37 In order for the transpiration method to work satisfactorily in studies of heterogeneous equilibria, the following conditions should be met:
(1) Reactions must be fast enough and flow rates must be slow enough to allow equilibration between gas and condensed phases.
(2) Adequate stirring of liquid phases must be maintained to provide uniform concentrations of reactants.
(3) The vapor pressures of condensed phases must be low enough to prevent significant loss by transport in the carrier gas.
(4) Reacting gases should be unassociated.
(5) An adequate means of removal and measurement of reactive gases from the flowing gas stream must be available.

The best evidence that these conditions have been met in the present system is described in Chapter III. The variation in flow rates and in the amount of reaction necessary to maintain equilibrium was used to test the validity of the first two conditions. The vapor pressure data for $\mathrm{BeF}_{2}{ }^{10}$ and LiF-BeF2 mixtures ${ }^{38}$ indicated that very little $\mathrm{BeF}_{2}$ would be vaporized. The vapor pressure of BeO at the experimental temperatures is insignificant. ${ }^{39}$ Although both $\mathrm{H}_{2} \mathrm{O}$ and HF are at least partially associated at room temperature, the dilute gases at melt temperatures are expected to be ideal.

Determinations of the partial pressures of HF and $\mathrm{H}_{2} \mathrm{O}$ over aqueous hydrofluoric acid solutions have been made by means of the transpiration method. ${ }^{40}$ Measurements were made over solutions of $10,20,30,50$, and. $70 \%$ hydrofluoric acid, at temperatures from 0 to $70^{\circ} \mathrm{C}$. The HF in the carrier gas stream was absorbed by an aqueous KOH solution. The difference between weight lost by the saturator and weight of HF found in gas stream was assumed to be the amount of water removed from the saturator. Since this difference could not be used in the present studies, a suitable method for measuring water was needed. Kemp investigated several methods of analysis. Condensation of samples in a cold trap with subsequent weighing and analysis for per cent HF was not satisfactory primarily because of the small size of the samples. Adsorption of the water by a suitable dessicant in a weighed drying tube was not satisfactory because HF was also adsorbed.

Finally, it was observed that a mixture of methanol and pyridine was suitable for removal of water from a flowing stream even in the presence of HF. Titration of the water with Karl Fischer Reagent could be performed in the vessel and since Karl Fischer Reagent contains excess methanol and pyridine, several successive titrations could be performed. Apparently the HF reacted with excess pyridine to form a fairly soluble pyridinium hydrofluoride which did not interfere with the titration.

Karl Fischer Reagent consists of $\mathrm{I}_{2}$ and $\mathrm{SO}_{2}$ dissolved in pyridine and methanol (actually the "stabilized reagent" contains methylcellosolve instead of methanol). Although the titration is straightforward, ${ }^{41}$ the reaction occurs in two steps:
$\mathrm{H}_{2} \mathrm{O}+\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}+\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N} \cdot \mathrm{SO}_{2}+\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N} \cdot \mathrm{I}_{2} \rightarrow 2 \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+} \mathrm{I}^{-}+\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}_{+} \int_{-}^{-\mathrm{SO}_{2}}$
$\left.\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}_{+}\right|_{-} ^{\mathrm{SO}_{2}}+\mathrm{CH}_{3} \mathrm{OH} \rightarrow \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NHOSO}_{2} \mathrm{OCH}_{3} \cdot$
When titrating $\mathrm{H}_{2} \mathrm{O}$ with Karl Fischer Reagent the endpoint corresponds to the first appearance of $I_{2}$. For macrotitrations the reagent serves as its own indicator; however, for microtitrations a more precise method is needed. Several authors have reported suitable circuits for the amperometric determination of the endpoint. The one actually used was quite similar to the one described by Nernitz. ${ }^{42}$

Equilibria
If the molten Iif-BeF2 system comes into contact with water vapor, hydrolysis occurs releasing some HF into the gas space and leaving some oxygen-containing species dissolved in the melt. For a closed system at equilibrium, the amount of HF and $\mathrm{H}_{2} \mathrm{O}$ in the gas phase will depend on (1) the amounts of HF and $\mathrm{H}_{2} \mathrm{O}$ initially introduced, (2) the solubility of HF
and $\mathrm{H}_{2} \mathrm{O}$ in the melt, (3) the concentration of oxide in the melt, (4) the concentration of hydroxide, a reactive intermediate (in the sense that it can exist only in the presence of HF and $\mathrm{H}_{2} \mathrm{O}$ ), in the melt, and (5) the amount of HF and $\mathrm{H}_{2} \mathrm{O}$ consumed in side reactions which do not influence the oxide reaction scheme.

If the above quantities are properly controlled or measured, useful equilibrium data can be obtained. The reaction of HF and $\mathrm{H}_{2} \mathrm{O}$ at high temperatures with the structural metal used (nickel) can be suppressed by the presence of $\mathrm{H}_{2}$. Side reactions are essentially eliminated if the purity of melts is sufficiently high. The solubility of HF in melts in the absence of oxygen species has been mentioned and is small compared with the best estimates of oxide solubility. It seems reasonable to assume that water solubility would be of the same order of magnitude as that of HF and the experimental results supported this. One method of controlling the oxide concentration would be saturation of the melt with a sparingly soluble oxide such as BeO. With the above conditions set, transpiration experiments can be used to control the amounts of HF and $\mathrm{H}_{2} \mathrm{O}$ introduced and to measure the hydroxide concentration indirectly through the material difference between influent and effluent gas streams.

For a $\mathrm{BeO}-$ saturated, $\mathrm{Ii} \mathrm{F}-\mathrm{BeF}_{2}$ melt with excess solid BeO present the following equilibrium is valid:
$\mathrm{H}_{2} \mathrm{O}(\mathrm{g})+\mathrm{BeF}_{2}(\mathrm{soln}) \rightleftharpoons 2 \mathrm{HF}(\mathrm{g})+\mathrm{BeO}(\mathrm{s})$.
If both HF and $\mathrm{H}_{2} \mathrm{O}$ are assumed to be ideal gases and if the thermodynamic activities of the condensed species are represented by "a", the equilibrium constant for the reaction would be

Since $a_{B e O}$ is 1 by definition, $K_{\mathrm{a}}=\left(\mathrm{P}_{\mathrm{HF}}\right)^{2} / \mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}{ }^{\mathrm{BeF}_{2}}=\mathrm{Q} / \mathrm{a}_{\mathrm{BeF}_{2}}$.
This equilibrium is independent of the presence or absence of hydroxide in the melt.

The quantity $\left(\mathrm{P}_{\mathrm{HF}}\right)^{2} / \mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}$ for BeO saturated melts, defined above as $Q$, can be abtained from determination of partial pressures in the gas phase alone. Thus $Q$, which is proportional to the activity of $\mathrm{BeF}_{2}$, would be equal to $\mathrm{K}_{\mathrm{a}}$ for the equilibrium involving pure liquid $\mathrm{BeF}_{2}$ at the same temperature. Determination of $Q$ for various temperatures and compositions of BeF2 provides the data necessary for thermodynamic calculations involving the melts.

The following additional equilibria involving oxide and hydroxide ions in the melt should also be considered. (The corresponding equilibrium quotients, which are shown, may be considered constant for a given LiF-BeF2 composition and temperature since at the low concentrations of oxide and hydroxide involved, the activity of $\mathrm{F}^{-}$and the activity coefficients $\gamma_{\mathrm{O}^{2-}}$ and $\gamma_{\mathrm{OH}^{-}}$can reasonably be assumed constant.) Since [ $\mathrm{F}^{-}$] is reasonably constant for a given melt composition, $\left[\mathrm{F}^{-}\right]$is incorporated into the equilibrium quotients.

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})+2 \mathrm{~F}^{-}(\text {soln }) \rightleftharpoons 2 \mathrm{HF}(\mathrm{~g})+\mathrm{o}^{2-}(\text { soln })
$$

$Q_{O}=\left(P_{H F}\right)^{2}\left[0^{2-}\right] / P_{H_{2} O}$
For oxide saturated melts [ $\mathrm{O}^{2-}$ ] is constant, hence

$$
Q_{0} /\left[0^{2-}\right]_{\text {sat }}=\left(P_{H F}\right)^{2} / P_{H_{2} \mathrm{O}}=Q .
$$

There are three reactions involving hydroxide in solution.

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})+\mathrm{F}^{-}(\mathrm{soln}) \rightleftharpoons \mathrm{HF}(\mathrm{~g})+\mathrm{OH}^{-}(\text {soln })
$$

$$
Q_{\mathrm{A}}=\left(\mathrm{P}_{\mathrm{HF}}\right)\left[\mathrm{OH}^{-}\right] / \mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}
$$

$\mathrm{H}_{2} \mathrm{O}(\mathrm{g})+\mathrm{O}^{2-}(\mathrm{soln}) \rightleftharpoons 2 \mathrm{OH}^{-}(\mathrm{soln})$
$Q_{b}=\left[\mathrm{OH}^{-}\right]^{2} /\left(\mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}\right)\left[\mathrm{O}^{2-}\right]$
and for a melt saturated with oxide where $\left[0^{2-}\right]$ is constant,
$Q_{B}=\left[\mathrm{OH}^{-}\right]^{2} / \mathrm{P}_{\mathrm{H}_{2} \mathrm{O}} \quad$.
$\mathrm{HF}(\mathrm{g})+\mathrm{O}^{2-}(\mathrm{soln}) \rightleftharpoons \mathrm{OH}^{-}(\mathrm{soln})+\mathrm{F}^{-}(\mathrm{soln})$
$Q_{c}=\left[\mathrm{OH}^{-}\right] /\left(\mathrm{P}_{\mathrm{HF}}\right)\left[\mathrm{O}^{2-}\right]$
and for a melt saturated with oxide,

$$
Q_{\mathrm{C}}=\left[\mathrm{OH}^{-}\right] / \mathrm{P}_{\mathrm{HF}}
$$

Note that not all of the equilibrium quotients are independent. Since $Q_{O}$ is independent of $\left[\mathrm{OH}^{-}\right]$and $Q_{A}$ is independent of $\left[\mathrm{O}^{2-}\right]$, these two equilibrium quotients are the most conveniently employed. Both $Q_{b}$ and $Q_{c}$ can be expressed as functions of $Q_{0}$ and $Q_{A}$. $Q_{b}=\left(Q_{A}\right)^{2} / Q_{0} \quad$ and $\quad Q_{c}=Q_{A} / Q_{0}$ The relationships for BeO saturated melts are given by

$$
Q_{B}=\left(Q_{A}\right)^{2} / Q \quad \text { and } \quad Q_{C}=Q_{A} / Q
$$

Stoichiometric relationships show that the number of protons in a given volume of effluent gas will be less than the number in the influent gas by the amount that has appeared as $\mathrm{OH}^{-1}$ added to the melt. If the proton level in the effluent gas stream exceeds the level in the influent stream, $\mathrm{OH}^{-}$ is being removed from the melt. The difference in $\mathrm{H}_{2} \mathrm{O}$ content between the influent and effluent gas streams corresponds to the total amount of oxide plus hydroxide being added to or removed from the melt. Iikewise, the difference in HF content between the influent and effluent gas streams corresponds to the amount of fluoride being added to or removed from the melt. For all experiments conducted, the change in fluoride was small enough so that the LiF-BeF2 concentration in the melt was assumed to be constant throughout a given experiment.

For simplicity in handling equations the following notation will be used:
wt of melt $=w(\mathrm{~kg})$
vol of gas (measured at $T$ ) through melt $=V$ (liter)
$\mathrm{V} / \mathrm{wRT}=\mathrm{W}\left(\right.$ mole $\left.\mathrm{kg}^{-1} \mathrm{~atm}^{-1}\right)$
$P_{\text {HF }}=a+b W \quad$ and $\quad P_{H_{2} \mathrm{O}}=c+d W$ (atm) for influent pressures (NOTE: When the aqueous $H F$ saturator was employed $b$ and $d$ were always 0 . When gas mixing was employed $b$ and $d$ were small negative numbers because small opening in valve tended. to gradually close.)
$P_{\mathrm{HF}}=\mathrm{x}$ and $\quad \mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}=\mathrm{y}$ (atm) for effluent partial pressures
$\left[0^{2-}\right]=r$
$\left[\mathrm{OH}^{-}\right]=\mathrm{s}$
The equilibrium quotients may now be expressed as
$Q=x^{2} / y, \quad Q_{0}=x^{2} r / y, \quad$ and $\quad Q_{A}=x s / y \quad$.
Saturated Melts
For constant, influent partial pressures of $\mathrm{H}_{2} \mathrm{O}$, HF, or both there will be an ultimate steady state condition in which the effluent partial pressures are not changing, hence $r$ and $s$ are constant. In fact $r$ will be constant at all times in a given experiment unless rate of reaction to form hydroxide and water exceeds the dissolving rate of solid BeO. The speed with which $x$ and $y$ approach a steady state is controlled primarily by $Q$ and $Q_{A}$. According to the equations described earlier, the difference in proton level of influent and effluent streams is equal to the change in hydroxide concentration. Thus,

```
ds/dW=(a+2c)-(x+2y) e
```

Both ds and $y$ may be eliminated by using the relationships $Q=x^{2} / y$ and $Q_{A}=x s / y$. Rearrangement of the former gives $y=x^{2} / Q$. Rearrangement and substitution into the latter gives $s=Q_{A} x / Q$, which may be differentiated to give $\mathrm{a} s=\left(Q_{A} / Q\right) d x$. Thus
$d x / d W=\left(Q / Q_{A}\right)\left[(a+2 c)-\left(x+2 x^{2} / Q\right)\right]$.
Separation of variables gives
$\frac{d x}{(a+2 c)-x-(2 / Q) x^{2}}=\left(Q^{2} / Q_{A}\right) d W \quad$.

Defining $(a+2 c)$ as $A$, this equation may be integrated to give
$\frac{1}{[1+(8 \mathrm{~A} / Q)]^{\frac{1}{2}}} \ln \frac{(4 / Q) x+1+[1+(8 \mathrm{~A} / Q)]^{\frac{1}{2}}}{(4 / Q) x+1-[1+(8 \mathrm{~A} / Q)]^{\frac{1}{2}}}=\left(Q / Q_{A}\right) W+$ constant $\quad$.

The correlation of experimental measurements with this equation is described in Chapter III. The computer program for this correlation was written by R. J. McNamee, Operations Analysis Division, ORGDP.

## Unsaturated Melts

For unsaturated melts the change in $r$ and $s$ can be determined by material balance. The difference between influent and effluent partial pressures of $\mathrm{H}_{2} \mathrm{O}$ corresponds to the change in total oxide concentration $(d r+d s) / d W=(c-y) \quad$.

The difference in proton levels corresponds to the change in hydroxide concentration just as in saturated melts
$\mathrm{ds} / \mathrm{dW}=(\mathrm{a}-\mathrm{x})+2(\mathrm{c}-\mathrm{y}) \quad$.
By difference
$d r / d W=(x-a)+(y-c) \quad$.
Combination of these equations with $Q_{A}=x s / y$ and $Q_{O}=x^{2} r / y$ could, in
principle, yield integral equations expressing $Q_{A}$ and $Q_{0}$ as a function of the measured quantities. However, the resulting pair of simultaneous differential equations could not be integrated. The following simultaneous differential equations were obtained by elimination of x and y from the expressions for $d r / d W$ and $d s / d W$ :
$\mathrm{ds} / \mathrm{dW}=(\mathrm{a}+2 \mathrm{c})-\left(Q_{0} \mathrm{~s} / Q_{A} \mathrm{r}\right)\left(1+2 \mathrm{~s} / Q_{A}\right)$
and
$d r / d W=\left(Q_{0} s / Q_{A} r\right)\left(1+s / Q_{A}\right)-(a+c) \cdot$
These equations could be solved in the differential form to obtain values of $r$ and $s$ as a function of $W$ for specified values of $Q_{O}$ and $Q_{A}$. If $r$, $s, Q_{0}$ and $Q_{A}$ are specified at a given $W$, values for $x$ and $y$ may be calculated.

The method of solution of the equations and the correlation of experimental data by this method are described in Chapter III. The computer program for this correlation, "FIASCO", was written by M. T. Harkrider, ORNL Mathematics Division.

## II. EXPERIMENTAL

Chemicals

## Gases

Comercial $\mathrm{H}_{2}$ was purified before use by passage through a deoxo unit, a magnesium perchlorate drying tube and, finally, a liquid $\mathrm{N}_{2}$ trap. Commercial He was passed through an ascarite trap, a magnesium perchlorate drying tube and, finally, a liquid $N_{2}$ trap. Anhydrous $H F$ was used directly from a commercial cylinder without further purification. B \& A reagent grade $48 \%$ hydrofluoric acid was used as the source of $\mathrm{HF}(\mathrm{g})$ and $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$. Melt Components

Beryllium fluoride was from Brush Beryllium Company (material to be used in preparing the Molten-Salt Reactor Experiment fuel salt). Lithium fluoride was $B$ \& $A$ reagent grade. Various mixtures were prepared by melting together weighed samples of the two components. Samples of the mixtures were withdrawn in filter sticks and analyzed for $\mathrm{Be}, \mathrm{Li}, \mathrm{F}$ and impurities ( $\mathrm{Fe}, \mathrm{Cr}, \mathrm{Ni}, \mathrm{Cu}$ and S). High purity BeO from Brush Beryllium Company was added to the melts which were used in studies of oxide saturated melts. Standard Reagents

Reagent grade KOH was used in the preparation of 0.1 N base which was standardized with potassium acid phthalate. Karl Fischer Reagent from Fisher Chemical Company (So-K-3) was standardized by direct addition of weighed aliquots of water.

## Apparatus

Experiments were carried out by means of a transpiration method. The stepwise sequence of processes was as follows:

Control of flow of
$\mathrm{H}_{2}$ carrier gas
$\downarrow$
Addition of $\mathrm{HF}(\mathrm{g})$,

Equilibration with
$\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$, or both

Removal of HF or $\mathrm{H}_{2} \mathrm{O}$ in standardized reagent $\downarrow$ Measurement of volume of $\mathrm{H}_{2}$ carrier gas

A complete flow diagram of the apparatus is shown in Figure 2.

## Flow Control Panel

The manifold gas pressures ( $\mathrm{H}_{2}$ and He ) were not constant but varied, generally, between 5 and 10 lb gauge. A pressure relief valve (Moore Products Company differential type flow controller, Model 63BD, modified form) was used to reduce this pressure to a constant value of 3.0 Ib gauge. The gas next passed through a Fisher-Porter Rotameter which was used only as a visual check of the flow rate. The pressure was measured with a 4 min. Ashcroft gauge graduated in $1 / 4-1 b$ divisions from 0 to 15 lb above atmos. pheric pressure. The brass needle valve with micrometer handle was from Nuclear Products Company as was the $1 / 3$ - 1 b check valve which was used to

Fig. 2. Complete Flow-Diagram for Apparatus.
prevent back flow of gas. The $\mathrm{H}_{2}$ line to the aqueous HF saturator was also connected to a water filled manometer from which the pressure immediately upstream of the saturator could be determined. The various pieces on the panel were connected by 1/4-in. Cu tubing using mechanical Swagelok fittings.

An alternate flow control system, identical with the above except for the $\mathrm{H}_{2} \mathrm{O}$ manometer, was used to control the carrier gas for the anhydrous HF system.

## Aqueous HF Saturator

When HF and $\mathrm{H}_{2} \mathrm{O}$ were both desired in the influent gas, aqueous solutions of HF were employed. The $\mathrm{H}_{2}$ from the flow control panel passed first through a dry bottle, next the filled saturator, and then another dry bottle which acted as a trap for liquid droplets. Both the bottles and the saturator were machined from Teflon bar stock. The two bottles were $2 \frac{1}{2}-i n$. diameter with a capacity of 300 ml . The saturator was a two-piece spiral gas-washing bottle (3-in. outside diameter top, 2-in. bottom) with approximately the same volume as the dry bottles. Lids for the three were screwtype with $45^{\circ}$ shoulders which made pressure seals. The tube openings were threaded for compression-type nuts which sealed the tubes in place when tightened. The connecting line from the flow control panel and between the bottles was of $1 / 4$-in. Teflon tubing.

The saturator and dry bottles were in a constant temperature bath, the temperature of which was used to control the partial pressures of HF and $\mathrm{H}_{2} \mathrm{O}$. The temperature could be controlled $\pm 0.1^{\circ} \mathrm{C}$ from 15 to $25^{\circ} \mathrm{C}$. The bath was continuously cooled by a water coil while heating was controlled by a mercury-mercury contact thermostat and an electronic relay.

## Anhydrous HF Mixing System

For studies requiring anhydrous $\mathrm{HF}(\mathrm{g})$, controlled gas mixing was employed. The manifold HF pressure was controlled by regulating the temperature of the HF supply cylinder. The flow of HF was controlled by a small-orifice Monel diaphragm valve. The HF flowed from the valve through a 6 -mil capillary to the mixing chamber, a $1 / 4-\mathrm{in}$. Cu tube about 3 in . long. The HF entered at one end of the mixing chamber; the $\mathrm{H}_{2}$ entered at the other end through a $1 / 8$-in. Cu tube which extended the length of the chamber to the point where the HF capillary ended. The mixed gases flowed out through a sidearm. This system was adajuted from one designed by G. Long which was suitable for HF pressures from about $3 \times 10^{-2} \mathrm{~atm}$ downward. 43

Reaction Vessel
The melts were contained in cylindrical vessels (2-in. diam, 15-in. long; or 4-in. diam, 15-in. long) constructed of Grade A nickel. Each vessel was equipped with the following: a thermocouple well and a gasinlet tube ( $1 / 4$-in. tubing) each of which reached to within $1 / 2$ in. of the bottom of the vessel; a cover gas line (1/4-in. tubing) with an attached 6-in. Ashcroft Duragauge graduated from 30-in. vac to $30-1 b$ gauge; and a sampling port (a $3 / 8$-in. pipe with the end closed by a $1 / 2$-in. Worcester ball valve). A sidearm on the sampling port of $1 / 4$-in. tubing served as the gas-outlet line.

The sampling port could be connected to either a sampling apparatus or an addition apparatus. These apparatus (developed and in common use in molten salt studies at $O R N L^{44}$ ) allow removal of samples from the melt in Cu filter sticks with subsequent transfer to a dry box under He
atmosphere, and addition of weighed salt samples to the melt under a dry He atmosphere.

The reaction vessel was located inside an upright tube furnace, the temperature of which was controlled by an L \& N Speedomax H Temperature Controller with Model s Recorder and a Chromel-Alumel thermocouple. The temperature was checked periodically with a calibrated Pt vs Pt-10\% Rh thermocouple and an L \& N K-2 Potentiometer.

The gas lines from the saturator and the $H F$ mixing chamber to the reaction vessel and from the vessel to the titration assembly were of $1 / 4$-in. Cu tubing. Monel sealed-diaphragm valves were connected by means of silver-soldered joints. Both the lines and valves were heated to about $100^{\circ} \mathrm{C}$ with heating tape as precaution against condensation or surface adsorption of the HF or $\mathrm{H}_{2} \mathrm{O}$. Mitration Assembly

The Karl Fischer titration vessel was a $300-\mathrm{ml}$ round-bottom flask with the following additions: two Pt wires fused through the bottom of the flask about $3 / 4$ in. apart; a sidearm added to the bottom to allow drainage of the flask; two buret tips (for $5-\mathrm{ml}$ Koch microburets with 150ml reservoir) fused through the top of the vessel about 3 in . apart. The solution was stirred by a small bar magnet under the Pt wires. Teflon gas-inlet and gas-outlet lines were fitted through a rubber stopper.

The endpoint was determined by an amperometric method using the "deadstop" technique. ${ }^{45}$ The indicator circuit consisted of the following: $1.5-\mathrm{v}$ de source, a $10^{4}$ ohm variable resistor, a 500 ohm variable resistor, the Pt electrodes, and a microammeter (all connected in series). With excess Karl Fischer Reagent present the variable resistors were adjusted
so that a current of more than $100 \mu \mathrm{a}$ was observed. With excess water present the current was less than $2 \mu$. The endpoint was taken as the point at which the current was $50 \mu \mathrm{a}$.

The KOH titration vessel was a $175-\mathrm{ml}$ test tube. Teflon gas-inlet and gas-outlet lines, and the tip of a $10-\mathrm{ml}$ Lab-Crest microburet were fitted through a rubber stopper. Phenolphthalein indicator was used. Gas Volume Measurement

The carrier gas from the titration assembly was bubbled through a bottle containing KOH solution (to remove acidic vapors from the Karl Fischer Apparatus) and then through a bottle containing $\mathrm{H}_{2} \mathrm{O}$ [to saturate with $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ at room temperature] before its volume was measured in a Precision Wet Test Meter. The gas-exit line from the Wet Test Meter was connected to a Bubble-0-Meter which was used to measure flow rates.

## Procedure

## Measurements

The primary experimental quantities needed were the partial pressures of HF and $\mathrm{H}_{2} \mathrm{O}$ over the melt.

Titrations.--Measurements for determination of partial pressures were made as follows:
(1) A measured volume of standardized reagent was added to a titration vessel.
(2) The time required for the flowing gas to neutralize the reagent was determined.
(3) The flow rate of gas was determined at room temperature by timing a soap bubble for 100 ml . Since diffusion of $\mathrm{H}_{2}$ through the bubble
would lead to lower indicated flow rates than the true flow rates, at least one bubble before and one bubble after the one being timed were employed to help decrease diffusion of $\mathrm{H}_{2}$.
(4) Usually, at least three successive titrations were carried out with a given reagent and then the gas flow was switched to the other titration vessel for a similar number of titrations.
(5) The initial volume for a series of titrations was recorded from the wet-test meter, which indicated continuously the total gas volume which had passed through the reaction vessel during an experiment. The meter could be read only to the nearest 10 ml , which was a precise enough reading for total volume but not for individual titrations. The gas volumes titrated were calculated from the flow rate and time of titration.
(6) The temperature of the wet-test meter, which was the temperature of the gas as it was being measured, was recorded.

Calculations.--The required calculations to evaluate the partial pressures were carried out as follows:
(1) The measured volume of gas was calculated by (Time of titration)/(Time per 100 ml ) $\times 100=\mathrm{ml}$ of gas.
(2) The number of millimoles of the component removed from the gas stream by the titration was calculated by ( ml reagent) (conc reagent) $=$ millimoles component ( HF or $\mathrm{H}_{2} \mathrm{O}$ ).
(3) The partial pressure of the component was calculated from ideal gas law by

(ml gas) •

Iimitations.--The apparatus as employed did pose some limitations on the procedure. The aqueous HF saturator as designed could not accommodate flow rates greater than $200 \mathrm{ml} / \mathrm{min}$ without bumping. For consistency, comparable flow rates were used with the anhydrous HF system.

Under operating conditions both the Karl Fischer titration vessel and the KOH titration vessel were checked to verify that they were able to remove quantitatively the $\mathrm{H}_{2} \mathrm{O}$ and HF , respectively, from the flowing gas stream. In both instances two vessels were set up in series and the leak-through from the first determined the second. The amounts of HF and $\mathrm{H}_{2} \mathrm{O}$ titrated in the downstream vessels were less than $0.1 \%$ of the amounts measured in the upstream vessels.

The Karl Fischer titration vessel was also checked against in-leakage of moisture from the atmosphere. The amount of Karl Fischer Reagent needed to maintain the endpoint with no gas flowing through the vessel was about $0.07 \mathrm{ml} / \mathrm{hr}$. This correction was applied to pressures below $1 \times 10^{-3} \mathrm{~atm}$ when it altered the observed results by as much as $1 \%$.

Since the titration vessels were operated at room temperature, in order to avoid condensation, the max pressures of HF and $\mathrm{H}_{2} \mathrm{O}$ were limited to the vapor pressures above aqueous HF solutions at the same temperature. 40

Even for pressures below these limits some surface adsorption was encountered. When the flowing gas stream was switched through the Karl Fischer apparatus, the $\mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}$ determined for the first few tenths of a liter would be lower than the following determination. Therefore, the first titration of about 0.3 ml Karl Fischer Reagent was not recorded after the switch was made. Dehydration of the Teflon was observed after the flowing gas was stopped. Additional Karl Fischer Reagent was necessary to
maintain the endpoint. (This was much in excess of the amount due to inleakage discussed above and due to the untitrated gaseous water in the dipline.) The same problem was not observed with $P_{H F}$ measurements, but usually a small aliquot of KOH was added to vessel during switching to allow stabilization of flow before titrations were begun.

## Systematic Errors

The preceding method of calculating partial pressures included the assumption that the pressure in the apparatus from the saturator to the wet-test meter was constant and that the amount of material was the same at every stage. The assumption was also made that the measured volume was equal to the volume of carrier gas plus reactive components, HF and $\mathrm{H}_{2} \mathrm{O}$. These assumptions were not completely valid, but it will be shown in the following sections that the resulting systematic errors were small. The following notation will be used in the discussion of systematic errors:
$T_{m}=$ temperature of melt, $O_{K}$
$T_{W}=$ temperature of wet-test meter, ${ }^{O_{K}}$
$P_{W}=$ total pressure at wet-test meter
$p_{W}=$ vapor pressure of water at $T_{W}$
$x$ and $y=$ partial pressures of HF and $\mathrm{H}_{2} \mathrm{O}$, respectively, at titrator
$n_{H F}$ and $\mathrm{n}_{\mathrm{H}_{2} \mathrm{O}}=$ moles of HF and $\mathrm{H}_{2} \mathrm{O}$ as measured at $\mathrm{T}_{\mathrm{W}}$, $P_{W}$
$\mathrm{V}_{\mathrm{W}}=$ measured volume on wet-test meter
$V_{a}=$ volume of dry carrier gas going through system measured at $P_{W}, P_{W}$
$V_{b}=$ volume of gas entering titration assembly at $T_{W}, P_{W}$.
Measured Volume.--The measured gas volume, $V_{w}$, was of the carrier gas which had been saturated with water at $T_{W}$, immediately prior to
entering the wet-test meter. The volume which should have been used in the pressure calculations was $\mathrm{V}_{\mathrm{b}}$. The volume of carrier gas corresponding to the measured volume is given by
$\mathrm{V}_{\mathrm{a}}=\mathrm{V}_{\mathrm{w}}\left(\mathrm{P}_{\mathrm{w}}-\mathrm{P}_{\mathrm{w}}\right) / \mathrm{P}_{\mathrm{w}}$.
The volume of HF and $\mathrm{H}_{2} \mathrm{O}$ entering the titration assembly may be calculated from the gas laws to be
$\left(\mathrm{n}_{\mathrm{H}_{2} 0^{R T}}\right) / \mathrm{P}_{\mathrm{W}}+\left(\mathrm{n}_{\mathrm{HF}} \mathrm{RT}_{\mathrm{w}}\right) / \mathrm{P}_{\mathrm{w}}$.
(The effect of any non-ideality of HF or $\mathrm{H}_{2} \mathrm{O}$ at the low partial pressures involved here is expected to be negligible.)

From Dalton's law of partial pressures
$\frac{y}{\left(n_{H_{2} O^{R T}}\right) / P_{W}}=\frac{x}{\left(n_{H F} R P_{W}\right) / P_{W}}=\frac{P_{W}-(x+y)}{V_{a}}$.

Substituting the value of $V_{a}$ from the above equation,
$y=\frac{\left[P_{w}-(x+y)\right] P_{w} n_{H_{2} O} R T_{w}}{V_{w}\left(P_{w}-P_{w}\right) P_{w}}$,
note that $P_{W}$ cancels, and by a parallel method
$x=\frac{\left[P_{W}-(x+y)\right] n_{H F} R_{W} T_{W}}{V_{W}\left(P_{W}-p_{W}\right)}$.

According to these calculations, the x and y values calculated in the preceding section should be multiplied by the factor $f$, where
$f=\frac{P_{w}-(x+y)}{P_{W}-P_{W}}$.
The max and min values for $f$ can be estimated. $P_{W}=$ atmospheric pressure; $(x+y)$ varies from 0 to 0.033 atm , but generally is between 0.013 and
0.020 atm; $\mathrm{P}_{\mathrm{W}}$ is between 0.029 and 0.035 depending on $\mathrm{T}_{\mathrm{W}}$. The maximum value for $f$ would be $1.00 / 0.965=1.037$. The minimum value for $f$ would be $0.967 / 0.971=0.996$. For the majority of measurements, $0.980 / 0.970 \leq f \leq 0.987 / 0.970 ; \quad 1.01 .3 \leq f \leq 1.0196 \quad$.

Thus the calculated partial pressures are too low by 1.0 to $2.0 \%$ due to the removal of HF and $\mathrm{H}_{2} \mathrm{O}$ and subsequent saturation with $\mathrm{H}_{2} \mathrm{O}$ vapor before the volume of carrier was measured.

Another effect, which exerts a minor influence on pressure measurements, is the pressure drop, between the gas space above the melt and atmospheric pressure, required to maintain bubbling through the titrator and wet-test meter. This drop was less than 0.01 atm, and would cause the measured values to be low by as much as $1.0 \%$.

Influent Pressure.--The influent partial pressures were measured with the gas bypassing the reaction vessel. The influent partial pressures are controlled by the saturator temperature and are independent of the total pressure. The total pressure in the saturator was less during the measurements of the influent gas composition than when the gas was passing through the melt by the pressure drop required to maintain bubbling, which was about 0.015 atm . This pressure drop results in an expansion of the gas as it enters the reaction vessel, hence the actual influent partial pressures of HF and $\mathrm{H}_{2} \mathrm{O}$ are less than the measured influent partial pressures by $1.5 \%$.

Hydrogen Diffusion.--According to published diffusion coefficients ${ }^{46}$ the diffusion of $\mathrm{H}_{2}$ out of the Ni vessel could be a few milliliters per minute at the elevated temperature of the vessel. Only the reaction vessel was sufficiently hot to allow diffusion of hydrogen.

The rate of diffusion was measured experimentally by pressurizing an empty vessel to 5 lb gauge and following the decrease in pressure as a function of time. The pressures were measured down to 10 in . vacuum. A control experiment with He was used to check against leakage. The following rates of diffusion (expressed as the volume of gas per second which would be measured at the wet-test meter; i.e. at $T_{W}$ and $P_{W}$ ) were determined: $700^{\circ} \mathrm{C}, 0.035 \mathrm{ml} / \mathrm{sec} ; 650^{\circ} \mathrm{C}, 0.025 \mathrm{ml} / \mathrm{sec} ; 600^{\circ} \mathrm{C}, 0.015 \mathrm{ml} /$ sec. The rate of diffusion of $\mathrm{H}_{2}$ out of a vessel containing salt should be no greater and probably not much less than for an empty vessel.

The influent partial pressures from the aqueous saturator were determined without loss of $\mathrm{H}_{2}$ by diffusion since the gas bypassed the vessel. If the influent gas were passed through a vessel with no salt present, the measured partial pressures would be greater due to this effect, by an amount dependent on the temperature and flow rate.

Most experiments were conducted with flow rates between 2.0 and 2.5 $\mathrm{ml} / \mathrm{sec}$. This means the apparent influent pressures would be from 1.4 to $1.75 \%$ higher at $700^{\circ} \mathrm{C} ; 1.0$ to $1.25 \%$ higher at $650^{\circ} \mathrm{C}$; and 0.60 to $0.75 \%$ higher at $600^{\circ} \mathrm{C}$ than the measured influent pressures. The difference would be less at lower temperatures.

Hydrogen diffusion did not play the same role when the anhydrous HF supply system was used. The flow of HF through the control valve was independent of the flow rate of $\mathrm{H}_{2}$, hence the amount of HF was determined as a function of time and the influent $P_{H F}$ was calculated from this value and the effluent flow rate.

The effect of diffusion of $\mathrm{H}_{2}$ out of the reaction vessel need not have been as great as indicated above. The mixing of the effluent gas,
primarily through turbulence, could have permitted re-equilibration of the gas with the melt. This would reduce the error caused by loss of hydrogen from the system by diffusion.

Dead-volume. --The preceding errors reflect the variations in pressure and mass of flowing gas. There is one additional error in the pressure determination at a given volume. This is the lag in measured pressures because of the volume of the gas space above the melt. The following additional notation will be used:
$T_{m}=$ temperature of gas above the melt, ${ }^{O_{K}}$
$V_{m}=$ volume of gas space above the melt
$P_{1}=$ partial pressure of HF or $\mathrm{H}_{2} \mathrm{O}$ leaving the melt
$P_{2}=$ measured partial pressure
$d V=$ increment of gas flowing through system as measured at $T_{W}, P_{W}$.
From the mixing process,
moles of substance entering $V_{m}=\left(P_{1} d V\right) /\left(R_{W}\right)$
moles of substance leaving $V_{m}=\left(P_{2} d V\right) /\left(R_{W}\right)$
change of moles in $\mathrm{V}_{\mathrm{m}}=\left(\mathrm{V}_{\mathrm{m}} \mathrm{dP}_{2}\right) /\left(\mathrm{RT}_{\mathrm{m}}\right)$.
Thus,
$\left(V_{m} \mathrm{PP}_{2}\right) /\left(\mathrm{RT}_{\mathrm{m}}\right)=\left(\mathrm{P}_{1} \mathrm{dV}\right) /\left(\mathrm{RT}_{\mathrm{w}}\right)-\left(\mathrm{P}_{2} \mathrm{dV}\right) /\left(\mathrm{RT}_{\mathrm{w}}\right)$
and rearranging,
$P_{1}=V_{m}\left(T_{W} / T_{m}\right)\left(d P_{2} / d V\right)+P_{2}$.
For most experiments, $\mathrm{V}_{\mathrm{m}}=0.400$ liters and $\mathrm{T}_{\mathrm{W}}=300^{\circ} \mathrm{K}$. When $\mathrm{T}_{\mathrm{m}}=773^{\circ} \mathrm{K}$, $\left(T_{W} / T_{m}\right)=(300 / 773)=0.388$ and when $T_{m}=973^{\circ} \mathrm{K},\left(T_{\mathrm{w}} / T_{\mathrm{m}}\right)=(300 / 973)=$ 0.308 .

Therefore, at $500^{\circ} \mathrm{C}$
$P_{1}=0.1552\left(\mathrm{dP}_{2} / \mathrm{dV}\right)+P_{2}$
and at $700^{\circ} \mathrm{C}$
$P_{1}=0.1232\left(d P_{2} / d V\right)+P_{2}$.
The most dramatic change in $\mathrm{P}_{2}$ occurred in the experiments when water was introduced into melts which contained very little oxide. The maximum rate of pressure change noted was $0.01 \mathrm{~atm} /$ liter. Therefore, $P_{1}=1.55 \times 10^{-3}+P_{2}$.

This large change occurred only during the first liter and only in the HF measurements. During this time $\mathrm{P}_{2}$ increased to about $1 \times 10^{-2}$ atm so that the error in these unusual circumstances was only about $10 \%$. At all other times the change was less than $1 \times 10^{-4} \mathrm{~atm} /$ liter and often less than 1 x $10^{-5} \mathrm{~atm} /$ liter. For all of these conditions the error would be much smaller than 1.0\%.

This treatment assumes no further equilibration after the bubble leaves the melt. If any did occur then application of the above equation would be an overcorrection.

Summary.--The combined effect of these systematic errors on the overall accuracy of the results will now be considered.

Due to the measured-volume error all observed partial pressures were 1.0 to $2.0 \%$ low. The other errors do not affect the observed partial pressures but do affect the material balance relationships used in treating the data.

The calculated values of $Q$ (i.e., $x^{2} / y$ ) are 1.0 to $2.0 \%$ low for all cases. This range is within the experimental scatter of the data. No bias is introduced in calculation of activities because of the extrapolation to pure $\mathrm{BeF}_{2}$. The extrapolated thermodynamic values for $\mathrm{BeF}_{2}$ (1) are well within the precision of literature data. No comparison of influent
and effluent pressures is required and diffusion of $H_{2}$ should not influence results.

The expected effects on $Q_{A},(x / y)\left[\mathrm{OH}^{-}\right]$, are within the scatter of the data. The quantity, $(x / y)$, will not be affected by any of the errors. The hydroxide concentration is based on proton material balance between influent and effluent gas. Thus, due to the error in measured influent pressures, the hydroxide concentration should be decreased by 1.5\%. Due to the error caused by diffusion of hydrogen, the hydroxide concentration should be increased by 0.5 to $1.75 \%$ depending on temperature and flow rate. Since the hydroxide concentration is proportional to $Q_{A}$, the calculated values for $Q_{A}$ could range from $1.0 \%$ high to $0.25 \%$ low. This range is well within the indicated scatter of data, with $Q_{A}$ generally known only to $\pm 10 \%$.

For unsaturated melts, $Q_{0}$ is based on the difference between oxygen material balance and proton material balance. $Q_{0}$ is subject to the same corrections as $Q_{A}$, hence it is from $1.0 \%$ high to $0.25 \%$ low. The quantities $Q_{B}$ and $Q_{C}$ are derived from $Q_{A}$ and $Q$, hence they are in error in the same manner.

Random Errors
In order to give a satisfactory estimate of the expected precision of the experimental measurements, the various random errors and their probable magnitudes are considered.

Melt Composition.--The melts were prepared by adding weighed samples of $\mathrm{BeF}_{2}$ and LiF to the reaction vessel. The precision of weighing and transferring samples to the vessel was about $\pm 0.2 \%$. The weight per cent of Li, Be and $F$ was determined chemically on filtered samples. The variation
in analyses of successive samples from the same melt was generally $\pm 4 \%$ for each constituent, which was clearly greater than the uncertainty based on weights of components. Since both LiF and BeF 2 are hygroscopic, small amounts of water were included in the weighed samples. Determination of moisture content of typical samples by the thermogravimetric method indicated 0.1 and $0.4 \%$ moisture, respectively. Thus, on the basis of the above uncertainties in weight and moisture content, the melt compositions, expressed as mole fraction $\mathrm{BeF}_{2}$, were probably known within $\pm 0.5 \%$.

The amounts of the impurities $\mathrm{Cr}, \mathrm{Cu}, \mathrm{Fe}, \mathrm{Ni}$ and S were determined in the starting materials, in filtered samples of the melt after it had been sparged with $H_{2}$ for more than 48 hr , and again immediately after sparging for 6 hr with a dilute mixture of HF and $\mathrm{H}_{2} \mathrm{O}$ in $\mathrm{H}_{2}$. All analyses were within the following range: Cr always less than $20 \mathrm{ppm}, \mathrm{Cu}$ always less than 100 ppm , Fe usually between 100 and 200 ppm , Ni usually less than 20 ppm , and S always less than 5 ppm . Total measured impurities only amount to about 350 ppm which is not significant in terms of melt composition.

The impurities could, however, cause some uncertainty in the partial pressure measurements if the impurities reacted to liberate or consume HF or $\mathrm{H}_{2} \mathrm{O}$ during an experiment. Consumption of HF would have occurred if sulfide had been present in concentrations greater than 5 ppm by the reaction of $\mathrm{s}^{2-}$ with HF in a manner analogous to the reaction of oxide with HF. 47 Since the impurity levels were not appreciably decreased during the $\mathrm{H}_{2}$ sparging, the impurities apparently were not reduced to the metallic state. The results of Blood's study on the stability of the difluorides of nickel, iron and chromium ${ }^{21}$ indicate they should eventually be reduced. However,
most of the reactions he studied required several days for equilibration. His results indicate that: the $\mathbb{N i}$ reaction vessel would not react with HF to produce $\mathrm{NiF}_{2}$ concentrations greater than 0.1 ppm with the highest $\left(\mathrm{P}_{\mathrm{HF}}\right)^{2 /} \mathrm{P}_{\mathrm{H}_{2}}$ ratios employed here; the Cr would have been in the $\mathrm{CrF}_{2}$ state for all $\left(\mathrm{P}_{\mathrm{HF}}\right)^{2} / \mathrm{P}_{\mathrm{H}_{2}}$ ratios above $1 \times 10^{-8}$ (true at all times except for extended stripping with $\mathrm{H}_{2}$ ); the $\mathrm{FeF}_{2}$ concentration could have varied between the time when $H_{2}$ was used and when $\left(\mathrm{P}_{\mathrm{HF}}\right)^{2} / \mathrm{P}_{\mathrm{H}_{2}}=4 \times 10^{-4} \mathrm{~atm}$.

The Fe probably did not react rapidly enough to interfere (or the analyses were in error) as indicated by the following experiment. Anhydrous $\mathrm{HF}-\mathrm{H}_{2}$ mixtures (approximately 0.01 atm HF ) were enployed to remove oxide and hydroxide from melt. After the melt was essentially free of oxide, the effluent $P_{H F}$ equaled the influent $P_{H F}$. The $H F$ was then stopped and $\mathrm{H}_{2}$ continued. The total amount of HF stripped out was about 5 ppm and was probably due to $H F$ solubility. If the Fe had been appreciably reduced, more $H F$ would have been detectable in the stripping gas.

Melt Temperature.-The temperature of the melt varied about $\pm 0.5^{\circ}$ during the furnace heating and cooling cycle. The observed temperature with the thermocouple at different depths in the melt did not vary more than $\pm 1.0^{\circ}$. Overall, the temperature of a melt was known and constant to $\pm 1.5^{\circ}$. One exception to the low temperature variation with dept occurred when large amounts of solid IiF were in the melt. In this case the temperature read about 15 to $20^{\circ}$ lower at complete insertion of the thermocouple than when the thermocouple was withdrawn about 1 in. from the bottom. Even in this case the temperature varied no more than $\pm 2^{\circ}$ when the thermocouple was withdrawn further. Apparently the solid LiF settled to the bottom and was not stirred by the bubbling, and as a
result, loss of heat out of the end of the vessel was faster than the transfer of heat from the liquid to unstirred solid.

Titer Precision.--A 25-liter reservoir of KOH was standardized. with potassium acid phthalate before initial use and again approximately 3 and 6 months later. All values agreed with the average value $\pm 0.1 \%$.

The $150-\mathrm{ml}$ reservoir of the Karl Fischer apparatus was filled as needed from quart bottles of Karl Fischer Reagent. The reagent was standardized each time the reservoir was filled and frequently thereafter. Water ( 0.050 to 0.080 g ) was added directly to the titration vessel from a weighing buret and the Karl Fischer titer determined. Successive titrations agreed within $\pm 0.3 \%$. Usually the concentration change from one standardization to the next would not exceed 1\%. The precision in measuring the concentration of Karl Fischer Reagent was $\pm 0.5 \%$.

The volumes of both KOH and Karl Fischer Reagent used in standardizations were large enough so that the uncertainties in reading the burets could be ignored. However, the much smaller volumes used during experimental titrations were known only to $\pm 1.0 \%$.

Wet-test Meter Temperature.--The wet-test meter temperature, which was the temperature of the gas as its volume was being measured, varied no more than $\pm 0.5^{\circ}$ during a given experiment. Due to the variation in temperature, the variation in measured volume is about $\pm 0.2 \%$, including the effect due to the change in vapor pressure of water.

Endpoint Precision.--The precision in the timing of endpoints was constant at $\pm 0.5 \%$ of the measured value.

Flow-rate Precision.--The precision in the timing of flow rates was 0.1 second per 100 ml . For a typical value of 50 seconds per 100 ml , this would amount to $0.2 \%$.

## Statistical Error Analysis

The probable error in the calculated quantities can be determined from the magnitude of random errors in the various measurements. If the contribution of each observable, $q_{i}$, to the calculated function, $Q$, is known and expressed as
$Q=f\left(q_{1}{ }^{a}, q_{2}{ }^{b}, \cdots \cdots, q_{n}^{m}\right)$,
and $(\Delta Q / Q) \times 100$ is $\%$ probable error in $Q$ and $\left(\Delta q_{i} / q_{i}\right) \times 100$ is $\%$ probable error in $q_{i}$, the contribution of errors can be calculated. If the errors follow a normal distribution, it can be shown ${ }^{48}$ that the following equation allows for partial cancellation of errors of opposite sign: $(\Delta Q / Q)^{2}=a^{2}\left(\Delta q_{1} / q_{1}\right)^{2}+b^{2}\left(\Delta q_{2} / q_{2}\right)^{2}+\cdots \cdots+m^{2}\left(\Delta q_{n} / q_{n}\right)^{2}$.
Evaluating the above equation numerically for each observable and taking the square root of both sides will give the probable error in the calculated quantity.

Volume of Gas Titrated.--
ml of gas $=\mathrm{f}$ (time of titration, time of flow measurement)
$(\Delta \mathrm{ml} \text { gas } / \mathrm{ml} \text { gas })^{2}=(0.005)^{2}+(0.002)^{2}=29 \times 10^{-6}$
$\%$ probable error in vol of gas $=0.54 \%$.
Millimoles $\mathrm{H}_{2} \mathrm{O}$ Titrated by Aliquot.--
millimoles $\mathrm{H}_{2} \mathrm{O}=f$ (conc Karl Fischer Reagent, vol Karl Fischer Reagent) $\left(\Delta \text { millimoles } \mathrm{H}_{2} \mathrm{O} / \text { millimoles } \mathrm{H}_{2} \mathrm{O}\right)^{2}=(0.005)^{2}+(0.010)^{2}=125 \times 10^{-6}$ $\%$ probable error in millimoles $\mathrm{H}_{2} \mathrm{O}=1.11 \%$.

Millimoles HF Titrated by Aliquot.--
millimoles $\mathrm{HF}=\mathrm{f}$ (conc KOH , vOl KOH$)$
$(\Delta \text { millimoles } \mathrm{HF} / \text { millimoles } \mathrm{HF})^{2}=(0.001)^{2}+(0.010)^{2}=101 \times 10^{-6}$ $\%$ probable error in millimoles $\mathrm{HF}=1.00 \%$.

## Pressure $\mathrm{H}_{2} \mathrm{O} .--$

$P_{\mathrm{H}_{2} \mathrm{O}}=\mathrm{f}$ (vol gas, millimoles $\mathrm{H}_{2} \mathrm{O}$, wet-test meter temp)
$\left(\Delta \mathrm{P}_{\mathrm{H}_{2} \mathrm{O}} / \mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}\right)^{2}=(0.0054)^{2}+(0.0111)^{2}+(0.002)^{2}=154 \times 10^{-6}$
$\%$ probable error in pressure $\mathrm{H}_{2} \mathrm{O}=1.24 \%$.
Pressure HF.--
$P_{H F}=f($ vol gas, millimoles HF, wet-test meter temp $)$ $\left(\Delta P_{H F} / P_{H F}\right)^{2}=(0.0054)^{2}+(0.010)^{2}+(0.002)^{2}=133 \times 10^{-6}$ \% probable error in $P_{H F}=1.15 \%$.

Equilibrium Quotients.--The exact relationship of $Q, Q_{A}$ and $Q_{0}$ to all of the variables cannot be expressed in the proper form to calculate the expected uncertainty. However, use of only the dependence on the pressure measurements would lead to $2.5,4.0$ and $4.7 \%$, respectively, as the most precise possible determinations. Both $Q_{A}$ and $Q_{O}$ depend on integral relationships between influent and effluent gas which increase the uncertainty still further.
III. RESULTS

Tabulation

Saturated Melts
Appendix A contains the data from each experiment performed on a saturated melt. The experiments are arranged according to a three digit "Run No." which indicates chronological order. Here, and throughout the text, numbers preceding "BeF2" denote mole fraction. In the 100 series the first experiments (101-123) were run in a 2 -in.-diam vessel on 305 g of $0.316 \mathrm{BeF}_{2}$ and 6 g BeO , whereas, for the later experiments (125-129), enough $\mathrm{BeF}_{2}$ was added to give $0.333 \mathrm{BeF}_{2}$.

In the 200 series a 4-in.-diam vessel was charged with 1522 g of $0.80 \mathrm{BeF}_{2}$ and 10 g BeO for the first experiments (201-213). After this composition was studied, enough LiF was added to give 0.70 (215-223), $0.60(225-233), 0.50(235-241), 0.40(245-255)$ and $0.333 \mathrm{BeFz}(257-273)$.

In the 400 series the first experiments (401-409) were run on 0.30 BeF2 obtained by adding 44 g LiF and 3.0 g BeO to the melt used in the 300 series. For the later experiments (413-423) 87 g additional LiF was added to give $0.25 \mathrm{BeF}_{2}$.

The parameters listed in Appendix A are:
$\mathrm{w}=\mathrm{wt}$ of melt, kg
$T=$ temperature of wet-test meter, ${ }^{\circ}{ }^{\circ} \mathrm{K}$
$a=$ influent $P_{H F}$, atm $\times 10^{3}$
$c=\operatorname{influent} \mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}$, atm $\times 10^{3}$.
The effluent partial pressures, $P_{H F}=x$ and $P_{H_{2} O}=y$, are tabulated (atm $\times 10^{3}$ ) with the corresponding initial and final values of W . Note that
the use of W allows consistent comparison of experiments independent of the weight of melt or temperature of gas-measurement. Unsaturated Melts

Appendix B contains the data from each experiment performed on an unsaturated melt. These experiments are also arranged according to a three digit "Run No." In the 300 series a 2 -in.-diam vessel was charged with 500 g of $0.333 \mathrm{BeF}_{2}$ and anhydrous HF was used to remove oxide from the melt. Measurements then were made while an aqueous-HF gas stream was being passed through the melt.

In the 500 series the first experiments (501-527) were run in a 2-in.diam vessel containing 500 g of $0.333 \mathrm{BeF}_{2}$. For the later experiments (529-539) enough LiF was added to give $0.273 \mathrm{BeF}_{2}$. Measurements were made both while anhydrous HF was being used to remove oxide from solution and while an aqueous-HF gas stream was being used to add oxide to solution.

In the 600 series a 2 -in.-diam vessel was charged with 424 g of 0.60 BeF2 for the first experiments (601-615). For the later experiments (617627) LiF was added to give 567 g of $0.40 \mathrm{BeF}_{2}$. Measurements were made during both the removal and addition of oxide.

The format of Appendix B is identical to that of Appendix A except that influent pressures are reported as $P_{H F}=a+b W$ and $P_{H_{2} \mathrm{O}}=c+d W$ when gas-mixing method was employed.

Determination of Equilibrium Quotients

The experimental data were correlated according to the model presented in Chapter I. Computer methods were developed for these correlations.

## Saturated Melts

The experiments fall into the following three groups:
Case I. Measurements were made while both $P_{H F}$ and $P_{H_{2} \mathrm{O}}$ were still changing but were stopped before steady state was reached.

Case II. Partial pressure measurements were made only after $P_{H F}$ and $P_{H_{2} \mathrm{O}}$ had reached steady state.

Case III. Measurements were made in both the changing- and steady-state regions.

The program was designed to handle all three cases with only Case I requiring additional input information. In all cases, since x and y were determined alternately, direct calculation of $Q$ would require interpolation, which was not very satisfactory where $x$ and $y$ were volume dependent.

The procedure of solution is outlined in the following steps:

1. For Case I, Q was specified as part of input information. For Cases II and III, Q was not specified; the computer started with the largest value of W and compiled average x and y as it moved to successively lower values of $W$ until the partial pressures became lower than the average to that point by a specified amount (usually 4\%). Safeguards were build in to prevent the computer prematurely terminating this process because of unusual scatter.
2. Using all of the partial pressures selected above, the average value of $x$ and the average value of $y$ were calculated and their standard. deviations were expressed at the $99 \%$ confidence level. The best $Q$ was calculated from these averaged partial pressures and its standard deviation was calculated from the deviation of its component parts.
3. Using the $Q$ calculated (or $Q$ provided if Case I), each observed $y$ was converted to a corresponding $x$ using the relationship $x=(Q y)^{\frac{1}{2}}$, for the initial region not used in the determination of $Q$.
4. Next, for each $x$ (observed or calculated from observed $y$ ) the quantity

$$
\log \frac{(4 / Q) x+1+[1+(8 A / Q)]^{\frac{1}{2}}}{(4 / Q) x+1-[1+(8 A / Q)]^{\frac{1}{2}}} \equiv f(W)
$$

(this relationship was derived in Chapter I) was determined and tabulated along with the midpoint, $W_{a}$, for each observation.
5. These $f(W)$ were now correlated according to the equation $f(W)=\frac{[1+(8 A / Q)]^{\frac{1}{2}} Q}{2.303}\left(1 / Q_{A}\right) W+$ constant
to obtain the best value of $Q_{A}$. The standard deviation in $Q_{A}$ was calculated by normal method for slope in a straight line correlation.
6. At this point a consistency check was made - the deviations from the best fit were determined to see if the observed values of $x$ were consistently on one side of the line and values of $x$ calculated from observed values of $y$ on the other side. If a difference had occurred, $Q$ could be readjusted or $Q_{A}$ determined from $x$ and $y$ separately.
Steps 1 and 2 complete the calculation for Case III. Steps 1 through 6 complete the calculation for each experiment.

Several examples of the various cases are given in Figures 3, 4, and 5. An example of Case $I$ is given in Figure 3a, with the observed values of $x$ and $y$ indicated by short bars. The line is generated by using the values for $Q$ and $Q_{A}$ determined by the correlation. Figure $3 b$ is a plot of $f(W)$ vs $W$, indicating the linearity of the relationship. Figure $4 a$ gives an example of Case III. The flat portion was used to determine $Q . Q_{A}$ was
determined from the initial region by holding $Q$ constant. A plot of $f(W)$ vs $W$ is given in Figure $4 b$ for the applicable region of the above run. Another example of Case $I$ is given in Figure 5 a showing the decrease in $x$ and $y$ when influent $H F$ and $\mathrm{H}_{2} \mathrm{O}$ were stopped and hydrogen sparging continued. Figure 5b gives a plot of $f(W)$ vs $W$ showing that the function also holds when influent pressures are zero.

The values obtained for $Q$ and $Q_{A}$ from all of the saturated-melt experiments are presented in Table 3. The values are arranged according to composition and temperature of melt. Run numbers are provided for cross reference with original data in Appendix A.

[^0]Unsaturated Melts
Determinations of equilibrium quotients involving oxide and hydroxide were based on material balance between influent and effluent gas. The differential equations needed for this correlation were developed in Chapter
I. These equations were:
$d r / d W=\left(Q_{0} s / Q_{A} r\right)\left(I+s Q_{A}\right)-[a+c+(b+d) W]$
and
$d s / d W=a+2 c+(b+2 d) W-\left(Q_{0} s / Q_{A} r\right)\left(1+2 s / Q_{A}\right) \quad$.
A computer program was developed for the simultaneous solution of these differential equations using the Runga-Cutta method of solution. ${ }^{49}$ This calculation required that the adjustable parameters, $Q_{O}, Q_{A}, r_{o}$, and $s_{o}$, and the fixed parameters, $a, b, c$, and $a$, be specified. With all of these quantities chosen, the change in $r$ and $s$ with respect to $W$ was calculated and new values estimated for $r$ and $s$ after the increment $\Delta W$. The cycle was then repeated stepwise and the process continued until a value of $W$ larger than a specified limit, $W_{\max }$, was reached. In order to determine $r$ and sprecisely without significant accumulative errors the step size, $\Delta W$, had to be restricted so that neither $r$ nor $s$ could change by more than $10 \%$ for any step. Values for $r$ and $s$ were tabulated at the various values of $W$ corresponding to the end of each step.

With both $r$ and $s$ know, both $x$ and $y$ could be calculated using the equilibrium relationships. If the relationships
$Q_{A}=x s / y \quad$ and $\quad Q_{O}=x^{2} r / y$
are solved simultaneously,
$x=Q_{O} s / Q_{A} r \quad$ and $\quad y=Q_{0} s^{2} / Q_{A}{ }^{2} r$.

These calculated values of x and y form smooth continuous curves although exact equations for the curves could not be expressed. The deviation of the observed $x$ and $y$ values from the calculated values was determined. A general least squares method was used to improve the fit. The partial derivatives of the $x$ and $y$ curves were determined numerically by making slight changes in each adjustable parameter ( $Q_{O}, Q_{A}, r_{O}, s_{o}$ ) successively. From the deviations and partial derivatives the adjustments in the parameters needed to minimize the squares of the deviations were determined.

With new values for $Q_{0}, Q_{A}, r_{o}$, and $s_{o}$ the new values for x and y were calculated. The least-square subroutine was repeated until the values for $Q_{O}, Q_{A}, r_{0}$, and $s_{0}$ were essentially constant as indicated by their being changed less than a preset limit (usually $1 \%$ ) in successive steps.

The method would not work when the initial guesses were not reasonably close to the correct values. Upper and lower limits were preset for the value of each parameter. If these limits were reached the calculation was terminated and the data resubmitted with different first guesses.

The "best" values for the parameters $Q_{0}, Q_{A}, r_{0}$, and $s_{0}$ are reported in Table 4. The indirect method for determining these values did not permit calculation of the standard deviations of these parameters. Since a large number of runs are reported for $0.333 \mathrm{BeF}_{2}$, the spread in the $Q_{0}$ and $Q_{A}$ values may be used as an indication of the uncertainties with which these are known. The values for $r_{0}$ and $s_{0}$ represent concentrations of oxide and hydroxide at the start of an experiment, hence their variations are mainly the result of differing histories of the melts. The runs are arranged according to composition and temperature with run numbers given for cross reference with the original data in Appendix B.

A measure of the goodness of fit is given in Table 5. The mean of the calculated $x$ curve is given with the standard deviation of the observed values of x from the calculated values along with the number of observed $x$ points. The corresponding information is also given for $y$. This tabular information does not give a complete picture of the correlation, hence the following figures are included to further show the relationships. Each figure consists of two plots: one showing the calculated values of $x$ and $y$ as a function of $W$ with the pressure data indicated by short bars, the other showing the values of oxide and hydroxide ( $r$ and $s$ ) at the same values of $W$ needed to obtain the calculated values of $x$ and $y$ for the parameters specified on each.

Figures 6 through 12 are all for $0.333 \mathrm{BeF}_{2}$. Figures 6 and 7 (Runs 303 and 305) show similar conditions $\left(600^{\circ} \mathrm{C}\right)$ except for the initial oxide concentration in the melt. Figure 8 (Run 306) shows the decrease in $x$ and y when the influent HF and $\mathrm{H}_{2} \mathrm{O}$ were stopped at the end of Run 305 and $\mathrm{H}_{2}$ sparging continued. Figures 9 and 10 (Runs 307 and 313) are for 700 and $500^{\circ} \mathrm{C}$, respectively. Figures 11 and 12 (Runs 501 and 511 ) show the behavior during higher-temperature $\left(650^{\circ} \mathrm{C}\right.$ ) and lower-temperature ( $550^{\circ} \mathrm{C}$ ) removal of oxide from the melt.

Figures 13 through 15 are for 0.273 BeF 2 . Addition of oxide is shown in Figure 13 (Run 533) and removal of oxide is shown in Figures 14 and 15 (Runs 535 and 539). Figure 16 (Run 607) shows removal of oxide from 0.600 $\mathrm{BeF}_{2}$ which is near the upper limit of this technique. Figure 17 (Run 621) shows the addition of oxide to $0.400 \mathrm{BeF}_{2}$.

## Validity of Results

The general agreement between the calculated and observed effluent partial pressures of HF and $\mathrm{H}_{2} \mathrm{O}$, in view of the variety of experimental conditions, supports the method of measurement and indicates that the equilibria assumed were correct and sufficient. Some specific examples which support these equilibria are given below.

Saturated Melts
The first clearcut indication of the formation of hydroxide in measurable amounts came from the variation of effluent pressures with respect to volume of carrier gas. When a mixture of HF and $\mathrm{H}_{2} \mathrm{O}$ was introduced into a BeO-saturated melt containing little or no hydroxide, the effluent partial pressures of HF and $\mathrm{H}_{2} \mathrm{O}(\mathrm{x}$ and y ) increased with the increase in volume of gas passed in such a manner that $x^{2} / y$ remained constant, while $x / y$ decreased. Since $Q_{O}=x^{2} r / y$ and $Q_{A}=x s / y$, the quantity $x^{2} / y$ would be constant when $r$ is constant (fixed by BeO saturation) and $x / y$ would decrease as s increases.

The influent partial pressures of HF and $\mathrm{H}_{2} \mathrm{O}$ were varied and the resulting $Q^{\prime}$ 's compared. Runs 101,103 , and 123 for 0.316 BeF 2 at $700^{\circ} \mathrm{C}$ (with reported $Q$ values of $2.18 \times 10^{-2}, 2.47 \times 10^{-2}$, and $2.13 \times 10^{-2}$, respectively) had influent pressures such that influent $\left(\mathrm{P}_{\mathrm{HF}}\right)^{2} /\left(\mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}\right)$ were $4.36 \times 10^{-2}, 4.46 \times 10^{-2}$, and $4.25 \times 10^{-3}$, respectively. Runs 105, 107, 109, and 111 for $0.316 \mathrm{BeF} z$ at $600^{\circ} \mathrm{C}$ (with reported $Q$ values of $4.61 \times 10^{-3}, 4.07 \times 10^{-3}, 4.09 \times 10^{-3}$, and $4.69 \times 10^{-3}$, respectively) also indicated that the observed $Q$ 's were independent of the influent pressures, with influent $\left(\mathrm{P}_{\mathrm{HF}}\right)^{2} /\left(\mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}\right)$ values being $6.52 \times 10^{-2}, 2.28 \mathrm{x}$ $10^{-2}, 5.54 \times 10^{-3}$, and $4.98 \times 10^{-3}$, respectively.

These runs include cases where the influent and effluent pressures were nearly identical and also where quite a bit of $H F$ was required to react with oxide to form water and the reverse ( $\mathrm{H}_{2} \mathrm{O}$ reacting with fluoride to form HF). All three gave Q's in agreement. In the early muns, the flow rate of carrier gas was varied from 50 to $150 \mathrm{ml} / \mathrm{min}$ and no variation in the effluent pressures was observed.

The $Q_{A}$ values determined using saturated melts were similarly found to be independent of the ratios of HF and $\mathrm{H}_{2} \mathrm{O}$ in the influent stream. Also, $Q_{A}$ was shown to be independent of whether hydroxide was being added or removed by the gas stream. For example, see the odd-even pairs 401-402, 405-406, and 407-408 in Table 3 for $0.300 \mathrm{BeF}_{2}$ at 652,601 and $700^{\circ} \mathrm{C}$, respectively.

The proton balance between influent and effluent gas streams, after the initial region where hydroxide was being formed, also attests to the validity of the measurement.

After completion of the 200 series the melt vas transferred from the vessel through a sintered nickel filter and the material on the filter examined by $x$-ray diffraction. The characteristic peaks for LiF-BeFz and BeO were observed. There was no indication of compound formation between BeO and the fluoride melt or of other constituents [such as $\mathrm{Li}_{2} \mathrm{O}$ or $\mathrm{Be}(\mathrm{OH})_{2}$ ]. Unsaturated Melts

In addition to the tests performed with saturated melts, the validity of $Q_{0}$ was checked by conducting experiments in which oxide was being added and also when oxide was being removed. The former, more precise results, and the latter were in reasonable agreement.
The total pressure of the reactive gases was varied by changing the temperature of the saturator with no noticeable effect on the $Q_{0}$ and $Q_{A}$ values.

## IV. DISCUSSION

The measured equilibrium quotients, $Q, Q_{A}$, and $Q_{O}$, were correlated with temperature and melt composition in terms of simple algebraic expressions. In the case of $Q$, wherein $K_{a}=Q / a_{\mathrm{BeF}_{2}}$, the resulting correlation can be used to derive a considerable amount of thermodynamic information about the LiF-BeF2 solutions and, by extrapolation, about pure $\mathrm{BeF}_{2}$ liquid. Combination of $Q$ and $Q_{O}$ can be used to obtain the concentration of oxide at $B e O$ saturation. The variation of $Q_{A}$ with melt composition and temperature reflects the stability of hydroxide in $\mathrm{LiF}-\mathrm{BeF}_{2}$ melts.

## Correlation of Q

For each composition, the $Q$ values were correlated according to the equation $\log Q=$ slope $(1 / T)+$ constant. The $Q^{\prime}$ s were weighted by an amount inversely proportional to their variance since all measurements did not follow the same parent distribution. The values of the parameters are presented in Table 6.

Since one of the primary objectives was determination of thermodynamic properties of $\mathrm{BeF}_{2}(\underline{1})$, extrapolation of these data as a function of $\mathrm{X}_{\mathrm{BeF}_{2}}$ to the pure liquid $\mathrm{BeF}_{2}$ was desirable. For a given temperature, $\log \left(Q / X_{\mathrm{BeF}_{2}}\right)$ vs $\left(X_{\mathrm{IjF}}\right)^{2}$
forms a parabola for the composition range 0.30 to $0.80 \mathrm{BeF}_{2}$, thus the Q values at various compositions were correlated by the function $\log \left(Q / X_{\operatorname{BeF}_{2}}\right)=k+I\left(X_{L i F}\right)^{2}+m\left(X_{L i F}\right)^{4}$.
From definition in Chapter $I$, $\log K_{a}=k$, therefore, correlation of $k$ as a function of $I / T$ will yield the thermodynamics of the desired reaction. Both I and $m$ also show linear dependence upon $1 / T$. For the coefficients
expressed according to $k=k^{\circ}+k^{\prime}(I / T)$, etc.
$k^{\circ}=3.900 \pm 0.019 \quad k^{\prime}=-4418 \pm 17$
$1^{\circ}=7.819 \pm 0.225 \quad I^{\prime}=-5440 \pm 218$
$\mathrm{m}^{0}=-12.66 \pm 0.60 \quad \mathrm{~m}^{\prime}=5262 \pm 513$.
From the above parameters, equations were generated for each experimental composition as a function of ( $1 / \mathbb{T}$ ). The smoothed parameters obtained are tabulated in Table 7. The lines generated by the smoothed parameters for the various experimental compositions are shown in Figure 18 along with $\log K_{a}$ vs ( $1 / T$ ) for pure $\mathrm{BeF}_{2}(1)$ based on the extrapolation. Figure 19 provides a measure of this correlation. The quantity $Q_{o b s} / Q_{c a l c}$ is shown for each experimental run. The standard deviation for each point is represented by a vertical bar.

Activity of $\mathrm{BeF}_{2}$ and LiF
Since $Q$ is equal to $K_{a}\left(a_{\mathrm{BeF}_{2}}\right)$,
$\log \left(\mathrm{Q} / \mathrm{X}_{\mathrm{BeF}_{2}}\right)=\log \mathrm{K}_{\mathrm{a}}\left(\mathrm{a}_{\mathrm{BeF}_{2}}\right) /\left(\mathrm{X}_{\mathrm{BeF}_{2}}\right)=\log \mathrm{K}_{\mathrm{a}}+\log \left(\mathrm{a}_{\mathrm{BeF}_{2}} / \mathrm{X}_{\mathrm{BeF}_{2}}\right) \quad$. By definition, $a_{\mathrm{BeF}_{2}}$ is unity for pure liquid $\mathrm{BeF}_{2}\left(\mathrm{X}_{\mathrm{BeF}_{2}}=1\right)$, therefore, $\log \left(\mathrm{a}_{\mathrm{BeF}_{2}} / 1\right)=0$. Since $X_{\mathrm{IiF}}=0$ at this point,
$\log K_{a}=k^{0}+k^{\prime}(1 / T) \quad$.
In order to solve for $\log \left(\mathrm{a}_{\mathrm{BeF}_{2}} / \mathrm{X}_{\mathrm{BeF}_{2}}\right)$, which is $\log \gamma_{\mathrm{BeF}_{2}}$, at any composition the value of $\log K_{a}$ must be subtracted from $\log \left(Q / X_{\mathrm{BeF}_{2}}\right)$ leaving $\log \gamma_{\mathrm{BeF}_{2}}=\left[I^{\circ}+I^{\prime}(I / T)\right] X_{\mathrm{LiF}}^{2}+\left[\mathrm{m}^{\circ}+\mathrm{m}^{\prime}(1 / T)\right] \mathrm{X}_{\mathrm{LiF}}^{4}$.

At a specified temperature, the variation in $\gamma_{\mathrm{BeF}_{2}}$ with composition is given by
$\log \gamma_{\mathrm{BeF}_{2}}=\alpha X_{\mathrm{LiF}}^{2}+\beta X_{\mathrm{LiF}}^{4}$.
Values for the parameters at three temperatures are presented below:

| $\begin{aligned} & \text { Temp } \\ & \left({ }^{\left(O_{C}\right)}\right. \\ & \hline \end{aligned}$ | $\alpha \pm \sigma$ |  | $\beta \pm \sigma$ |  |
| :---: | :---: | :---: | :---: | :---: |
| 500 | $0.783=$ | 0.380 | -5.85 | $\pm 0.89$ |
| 600 | 1.589 | 0.356 | -6.66 | 0.85 |
| 700 | 2.229 | 0.338 | -7.25 | 0.80 |

The quoted uncertainties in $\alpha$ and $\beta$ lead to an average uncertainty of $\pm 0.10$ units in $\log \gamma_{\mathrm{BeF}_{2}}$. From these uncertainties the values $100^{\circ}$ apart would overlap within the quoted uncertainty, but the values for 500 and $700^{\circ} \mathrm{C}$ definitely do not overlap.

According to the Gibbs-Duhem Equation, if the activity (or activity coefficient) of one component is known as a function of composition, the other can be determined by integration of the equation
$\alpha \ln \left(\gamma_{2}\right)=-X_{1} / X_{2} d \ln \left(\gamma_{1}\right) \quad$.
From the equations given for $\log \gamma_{\mathrm{BeF}_{2}}$ as a function of composition at specified temperatures, integration was carried out as follows:
$\log \gamma_{\mathrm{BeF}_{2}}=\alpha X_{\mathrm{LiF}}^{2}+\beta X_{\operatorname{LiF}}^{4}$
$d \log \gamma_{\mathrm{BeF}_{2}}=\left(2 \alpha X_{\mathrm{LiF}}+4 \beta X_{\mathrm{LiF}}^{3}\right) d X_{\mathrm{LiF}}$
$d \ln \gamma_{L i F}=-\left[\frac{\left(1-X_{L i F}\right)}{X_{L i F}}\right](2.303)\left(20 X_{L i F}+4 \beta X_{L i F}^{3}\right) d X_{L i F}$
$\ln \gamma_{L i F}=(2.303) \int\left(-2 \alpha+20 X_{L i F}-4 \beta X_{I i F}^{2}+4 \beta X_{I i F}^{3}\right) d X_{L i F}$ $\log \gamma_{\mathrm{IjF}}=-2 \alpha X_{\mathrm{IiF}}+\alpha X_{\mathrm{LiF}}^{2}-(4 / 3) \beta X_{\mathrm{LiF}}^{3}+\beta X_{\mathrm{LiF}}^{4}+C$.

Tvo methods for evaluating $C$ for various temperatures were considered. For a given temperature, if $\gamma_{\mathrm{IiF}}$ is known for one cormposition, C can be determined and, hence, $\gamma_{\text {LiF }}$ determined for all compositions. First,
$\gamma_{\text {LiF }}$ was calculated from the reported composition at LiF liquidus at various temperatures where $a_{\mathrm{ILi}} \equiv 1$ and $\gamma_{\mathrm{IjF}} \equiv 1 / X_{\mathrm{IiF}}$. The values for $\gamma_{\text {LiF }}$ at the various temperatures were determined from the published phase diagram ${ }^{2}$ which was presented in Chapter I. The second method involved the use of the $Q$ values for BeO-saturated melts in contact with solid LiF to determine the $X_{\text {LiF }}$ at saturation. (The measured $Q$ 's are tabulated in Table 3 and the parameters for smoothed fit are given in Table 6.) The equations for $\log a_{\mathrm{BeF}_{2}}$ as a function of conposition and $\log a_{\mathrm{BeF}_{2}}$ at LiF saturation were solved simultaneously to obtain $X_{\text {IiF }}$. With the concentration of $\operatorname{LiF}$ at $a_{\text {LiF }}=1$ known, $\gamma_{\text {LiF }}$ could be evaluated. The following values for $C$ were obtained by the two methods.

|  | From Thoma's Phase Diagram |  |  | From Solution of Equations |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { Temp } \\ & \left({ }^{\circ} \mathrm{C}\right) \end{aligned}$ | $\mathrm{X}_{\mathrm{BeF} 2}$ | $\gamma_{\text {Ii } \mathrm{F}}$ | C | $\mathrm{X}_{\mathrm{BeF} 2}$ | $\gamma_{\text {LiF }}$ | C |
| 500 | 0.329 | 1.490 | -0.299 | 0.321 | 1.473 | -0.328 |
| 600 | 0.280 | 1.389 | +0.083 | 0.281 | 1.391 | +0.086 |
| 700 | 0.208 | 1.263 | +0.283 | 0.256 | 1.344 | +0.451 |

Agreement of values of $C$ determined by both methods is very good at 500 and 600 but not at $700^{\circ} \mathrm{C}$. Although LiF saturation at $700^{\circ} \mathrm{C}$ occurs at 0.208 BeF 2 , the value of C corresponding to a calculated saturation value of $0.256 \mathrm{BeF}_{2}$ was considered more acceptable because the parabolic function does not fit the data well below $0.30 \mathrm{BeF}_{2}$. In fact, at 0.25 BeF 2 (data at 650 and $700^{\circ} \mathrm{C}$ ) the fit is very poor.

Other empirical expressions were tried in an attempt to improve the fit in this region. No improvement was obtained using expressions containing additional odd-powers of $X_{\text {LiF }}$, but a very good fit was obtained from 0.25 to $0.50 \operatorname{BeF}_{2}$ by using an equation containing $X^{2}, X^{4}$, and $X^{6}$
terms. Correlation of the data at $700^{\circ} \mathrm{C}$ gave the following equation:
$\log \left(Q / X_{\mathrm{BeF}_{2}}\right)=-0.723+4.094 \mathrm{X}_{\mathrm{LiF}}^{2}-16.64 \mathrm{X}_{\mathrm{LiF}}^{4}+12.51 \mathrm{X}_{\mathrm{LiF}} \quad$.
This equation should be compared with the correlation using only $X^{2}$ and $\mathrm{X}^{4}$ terms:
$\log \left(Q / X_{\mathrm{BeF}_{2}}\right)=-0.640+2.229 \mathrm{X}_{\mathrm{LiF}}^{2}-7.25 \mathrm{X}_{\mathrm{LiF}} \cdot$
Both fit equally well between 0.33 and $0.50 \mathrm{BeF}_{2}$, but the former fits better for concentrations below $0.33 \mathrm{BeF}_{2}$ and the latter fits better for concentrations above $0.50 \mathrm{BeF}_{2}$. In order to obtain values for $\gamma_{\mathrm{BeF}_{2}}$ from the former equation, the constant term was adjusted to yield the same value of $\gamma_{\mathrm{BeF}_{2}}$ (at $0.40 \mathrm{BeF}_{2}$ ) as was given by the simpler expression used to express activities above $0.30 \mathrm{BeF}_{2}$. The expression obtained for $\log \gamma_{\mathrm{BeF}_{2}}$ was given by:
$\log \gamma_{\mathrm{BeF}_{2}}=-0.0382+4.094 \mathrm{X}_{\mathrm{IJF}}^{2}-16.64 \mathrm{X}_{\mathrm{LiF}}+12.51 \mathrm{X}_{\mathrm{IiF}}^{6}$.
The Gibbs-Duhem integration was carried out on this equation in order to obtain the expression for $\log \gamma_{\text {LiF }}$ :

$$
\begin{aligned}
\log \gamma_{L i F}= & -8.188 X_{L i F}+4.094 X_{L i F}^{2}+22.20 X_{L i F}^{3}-16.64 X_{L i F}^{4}-15.01 X_{\mathrm{LiF}}^{5} \\
& +12.51 X_{L i F}^{6}+\mathrm{C} .
\end{aligned}
$$

If this equation is solved simultaneously with the equation for $\log \mathrm{a}_{\mathrm{BeF}_{2}}$ at LiF saturation, the concentration equals $0.208 \mathrm{BeF}_{2}$ (the same as reported by Thoma) and the value of $C$ equals 1.124 .

Figure 20 shows a plot of $\log \gamma_{\mathrm{BeF}_{2}}$ and $\log \gamma_{\mathrm{LiF}}$ as a function of composition at 500,600 , and $700^{\circ} \mathrm{C}$. The dashed lines indicate the values a.t $700^{\circ} \mathrm{C}$ (below $0.30 \mathrm{BeF}_{2}$ ) when the equation with the $\mathrm{X}^{6}{ }_{\mathrm{LiF}}$ term was used. (The overall fit was not improved by using the extra term, hence the simpler form was used for the more general correlation.) The dotted line indicates the values of $\log \gamma_{\text {LiF }}$ at which the solid LiF phase would appear
and the values of $\log \gamma_{\mathrm{BeF}_{2}}$ at which the pure liquid $\mathrm{BeF}_{2}$ phase would appear.

The (-...-.) line shows the predicted behavior of $\log \gamma_{\mathrm{BeF}_{2}}$ on the basis of a simple model in which, for the region $0.33-1.0 \mathrm{BeF} 2$, the components are redefined as $\mathrm{BeF}_{2}$ and $\mathrm{Li}_{2} \mathrm{BeF}_{4}$ and the activity of $\mathrm{BeF}_{2}$ is
 lated to $X_{\mathrm{BeF}_{2}}$, the mole fraction in LiF-BeF2 mixtures, by
$\mathrm{X}_{\mathrm{BeF}_{2}}=\left(3 \mathrm{X}_{\mathrm{BeF}_{2}}-1\right) / 2 \mathrm{X}_{\mathrm{BeF}_{2}}$.
Since $a_{\mathrm{BeF}_{2}}=X_{\mathrm{BeF}_{2}}$ as defined above, the activity coefficient of $\mathrm{BeF}_{2}$ in $\mathrm{Li} \mathrm{F}-\mathrm{BeF}_{2}$ mixtures is given by
$\gamma_{\mathrm{BeF}_{2}}=\left(3 \mathrm{X}_{\mathrm{BeF}_{2}}-1\right) / 2 \mathrm{X}_{\mathrm{BeF}_{2}}$.
This procedure of redefining components is similar to the method of Flood and Urnes; ${ }^{50}$ however, the assumed proportionality of $\mathrm{a}_{\mathrm{BeF}_{2}}$ to i.ts mole fraction is purely arbitrary and the resulting correlation, which is rather good, is, therefore, entirely empirical. It might be more reasonable in this model to expect $a_{\mathrm{BeF}_{2}}$ to be proportional to the product of the cation fraction of $\mathrm{Be}^{2+}$ and the anion fraction of ( $\mathrm{F}^{-}$) squared [i.e., $\mathrm{a}_{\mathrm{BeF}_{2}}$ proportional to $\left(\mathrm{X}_{\mathrm{BeF}_{2}}\right)^{3}$ ], the melt being considered to be a simple mixture of the four ions $\mathrm{Li}^{+}, \mathrm{Be}^{2+}, \mathrm{F}^{-}$, and $\mathrm{BeF}_{4}^{2-}$. In order to rationalize the proportionality of $\mathrm{a}_{\mathrm{BeF}_{2}}$ to $\mathrm{X}_{\mathrm{BeF}_{2}}$ it seems necessary to adopt one of the following unattractive models for the components
$\mathrm{Ii}_{2} \mathrm{BeF}_{4}$ (undissociated) $+\mathrm{BeF}_{2}$ (undissociated)
or
$\mathrm{Ii}_{2}{ }^{2+} \mathrm{BeF}_{4}{ }^{2-}+\mathrm{Be}^{2+} \mathrm{BeF}_{4}{ }^{2-}$.
A more realistic approach to an interpretation of the behavior of $\mathrm{a}_{\mathrm{BeF}_{2}}$ and $\mathrm{a}_{\mathrm{LiF}}$ can perhaps be made in terms of models such as have been
proposed by F $\phi$ rland. ${ }^{51}$ According to this model $\mathrm{BeF}_{2}(1)$ is assumed to be a three-dimensional polymer of $\mathrm{BeF}_{4}{ }^{2-}$ tetrahedra with common corners, and the addition of LiF is assumed to break the Be-F-Be bonds. However, no such correlation will be attempted here.

Two features of the observed variation of $a_{\mathrm{BeF}_{2}}$ are especially noteworthy:
(1) The rapid drop in $\gamma_{\mathrm{BeF}_{2}}$ as $X_{\mathrm{BeF}_{2}}$ approaches 0.33 , at all temperatures, suggests the formation of $\mathrm{BeF}_{4}{ }^{2-}$ ion.
(2) The temperature coefficient of $\gamma_{\mathrm{BeF}_{2}}$ indicates increasing positive deviations from Raoult's law with increasing temperature at high $X_{\mathrm{BeF}_{2}}$ values.
The activities of $\mathrm{BeF}_{2}$ and LiF were calculated from the activity coefficients as a function of composition and temperature. The activities at 500,600 , and $700^{\circ} \mathrm{C}$ are shown in Figure 21. The plot of activities, which should be proportional to the partial pressures of $\mathrm{BeF}_{2}$ and LiF, corresponds to the predicted behavior of a system showing incomplete miscibility. ${ }^{52}$ since the positive deviations increase with temperature, these data seem to indicate that the system has a lower consolute temperature near $700^{\circ} \mathrm{C}$ and $0.80 \mathrm{BeF}_{2}$. Although the number of determinations of Q in this area is not extensive enough to definitely show the formation of two liquid phases, the indication is strong enough to warrant further investigation of this possibility. To date there is no clearcut evidence of partial immiscibility in the LiF-BeFz system although various investigators have considered the possibility of such occurrence. ${ }^{53-55}$ The MgO$\mathrm{SiO}_{2}$ system, which has frequently been compared with the LiF-BeF2 system, ${ }^{1}$ indeed does show a miscibility gap. At least one case has been reported
for a similar fluoride melt. At low LiF concentrations in the system, LiF-BeF $2-\mathrm{ZrF}_{4}$, evidence was obtained from quenched samples that two immiscible liquids were formed above the $\mathrm{ZrF}_{4}$ primary phase field. 56

The LiF activity exhibits large positive deviations at low BeF 2 concentrations; however, it should be kept in mind that these activities are referred to the solid rather than the supercooled liquid (if the latter were used as the reference state, all of the activities would be lower). The activities reported in the present work are in general agreement with previous measurements (sumnarized in Table 2). The largest discrepancy is in the value for LiF at $0.50 \mathrm{BeF}_{2}$ reported by Berkowitz and Chupka. 22 The value for LiF by Büchler ${ }^{24}$ is in reasonable agreement. Also, Büchler obtained greater activities for $\mathrm{BeF}_{2}$ at higher temperatures. ${ }^{23}$ Special attention should be given to the value reported for 0.67 BeF 2 (displaying very large positive deviations) which corresponds very closely to present values. This agreement is particularly gratifying since three completely different techniques have been used to obtain the values. Also, the previous studies were performed with melts which did not have Beo present. The presence of Beo would not be expected to affect the activities since BeO is only slightly soluble. Beryllium oxide could not have affected the Gibbs-Drhem integration since BeO was always present as a saturating phase, thereby restricting its activity to unity.

The expression for the relative partial molal heat content is given by:

From the expression for $\log \gamma_{\mathrm{BeF}_{2}}$, the appropriate differentiation may
be carried out to obtain
$\frac{\partial \log \gamma_{\mathrm{BeF}_{2}}}{\partial T}=-\left(I^{\prime} X_{L i F}^{2}+m^{t} X_{L i F}^{4}\right)(I / T)^{2}$.
Therefore,
$\left(I^{\prime} X_{L_{i F}}+\mathrm{m}^{\mathrm{r}} \mathrm{X}_{\mathrm{LiF}}\right)=\left({\overrightarrow{\mathrm{H}_{\mathrm{BeF}}^{2}}}-\mathrm{H}_{\mathrm{BeF}_{2}}^{\mathrm{O}}\right) / 2 \cdot 303 \mathrm{R}$
and
$\left(\bar{H}_{\mathrm{BeF}_{2}}-\mathrm{H}_{\mathrm{BeF}_{2}}^{\mathrm{O}}\right)=2.303 \mathrm{R}\left[(-5440 \pm 218) \mathrm{X}_{\mathrm{LiF}}^{2}+(5262 \pm 513) \mathrm{X}_{\mathrm{LiF}}^{4}\right] \quad$.
Values for the relative partial molal heat contents at various compositions are tabulated below:

Since the activity coefficient of $\mathrm{BeF}_{2}$ is given by an analytical expression, the excess chemical potential of $\mathrm{BeF}_{2}$ can be directly calculated from
$\mu_{\mathrm{BeF}_{2}}^{\mathrm{E}}=\mathrm{RT}$ In $\gamma_{\mathrm{BeF}_{2}}$.
Since $\ln \gamma_{\mathrm{BeF}_{2}}$ is a function of temperature, this equation does not lend itself to easy tabular or graphic presention (unless in a plot similar to Figure 20); however, the analytical expression should be useful for further calculations involving the excess chemical potential.

Table 6. Parameters from Correlation of $Q$ as a Function of Temperature at Specified Compositions

Fig. 20. Activity Coefficients of LiF and BeF 2 in Mixtures.

Fig. 21. Thermodynamic Activities of LiF and $\mathrm{BeF}_{2}$ in Mixtures.

Thermodynamics of $\mathrm{BeF}_{2}$ (1)
From the correlation of $Q$ as a function of temperature and composition for the reaction
$\mathrm{BeF}_{2}(1)+\mathrm{H}_{2} \mathrm{O}(\mathrm{g}) \rightleftharpoons \mathrm{BeO}(\mathrm{s})+2 \mathrm{HF}(\mathrm{g})$
involving pure liquid BeF2, the equation expressing equilibrium constant values is
$\log K_{a}=(3.900 \pm 0.019)-(4418 \pm 17)(1 / T)$
or
$\Delta F=-(17.85 \pm 0.09) T+(20,217 \pm 78)$.
From this equation, the $\Delta H_{\text {reaction }}$, and $\Delta S_{\text {reaction }}$ are $20.22 \mathrm{kcal} / \mathrm{mole} \mathrm{BeF} 2$ and $77.85 \mathrm{eu} / \mathrm{mole} \mathrm{BeF}_{2}$, respectively. As indicated in Chapter $I$, the thermodynamic values of $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$, $\mathrm{HF}(\mathrm{g})$, and $\mathrm{BeO}(\mathrm{s})$ are fairly well established. Thus, by using these values and the relationships from the above reaction, new values for $\Delta F_{f}^{\circ}, \Delta H_{f}{ }_{f}, \Delta S_{f}^{\circ}$, and $S^{\circ}$ of $B e F_{2}(\underline{1})$ can be calculated. These are tabulated below along with the reported values from JANAF. ${ }^{4}$

| $\mathrm{BeF}_{2}(\underline{1}$ ) | at | $800^{\circ} \mathrm{K}$ JANAF | $\begin{gathered} 800^{\circ} \mathrm{K} \\ \text { Present Work } \end{gathered}$ | $1000^{\circ} \mathrm{K}$ <br> JANAF | $\begin{gathered} 1000^{\circ} \mathrm{K} \\ \text { Present Work } \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\Delta F^{\circ}{ }_{f}$ |  | -213.57 | -213.60 | -207.08 | -208.46 |
| $\triangle \mathrm{H}^{\circ} \mathrm{f}$ |  | -240.11 | -234.49 | -238.92 | -234.26 |
| $\Delta S^{\circ}{ }_{f}$ |  | -33.18 | -26.11 | -31.84 | -25.80 |
| $S^{\circ}$ |  | 30.66 | 37.74 | 35.36 | 41.35 |

While the present values are not in close agreement with the published values, they provide the most direct experimental method of evaluating the thermodynamic properties of $\mathrm{BeF}_{2}(\underline{1})$. If these values for $\mathrm{BeF}_{2}(\underline{1})$ are combined with the data of Greenbaum, et al. ${ }^{10}$ for the vapor pressures of $\mathrm{BeF}_{2}(\mathrm{I})$, new values for the thermodynamics of $\mathrm{BeF}_{2}(\mathrm{~g})$ can be obtained. These are tabulated below along with the values reported in JANAF.

| $\mathrm{BeF}_{2}(\mathrm{~g})$ |  | $800^{\circ} \mathrm{K}$ <br> JANAF | $\begin{gathered} 800^{\circ} \mathrm{K} \\ \text { Present Work } \\ \hline \end{gathered}$ | $\begin{aligned} & 1000^{\circ} \mathrm{K} \\ & \text { JANAF } \end{aligned}$ | $\begin{gathered} 1000^{\circ} \mathrm{K} \\ \text { Present Work } \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\Delta F^{\circ}{ }_{f}$ |  | -192.02 | -191.31 | -192.92 | -193.91 |
| $\Delta H^{\circ}{ }_{f}$ |  | -192.29 | -181.24 | -192.63 | -181.01 |
| $\Delta S^{\circ}{ }_{f}$ |  | -0.34 | 1.25 | -0.71 | 1.29 |
| $s^{\circ}$ |  | 63.50 | 76.4 | 66.49 | 80.1 |

The values of $\Delta H_{f}{ }_{f}$ and $S^{\circ}$ of $\mathrm{BeF}_{2}(\mathrm{~g})$ reflect significant difference between these results and those of Greenbaum, et $\frac{\mathrm{al} .}{} .^{5}$ for the reaction
$\mathrm{BeO}(\mathrm{s})+2 \mathrm{HF}(\mathrm{g}) \rightleftharpoons \mathrm{BeF}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{g}) \quad$.
Since the values of $\Delta F^{\circ}{ }_{f}$ from the two methods are in reasonable agreement, the greatest source of difference must be in the temperature dependence of the equilibrium quotients.

In addition to the thermodynamic properties of $\mathrm{BeF}_{2}(\underline{1})$ and $\mathrm{BeF}_{2}(\mathrm{~g})$, the present study provides a means of determining thermodynamic properties of $\mathrm{BeF}_{2}(\mathrm{~s})$ through determination of the heat of fusion, $\Delta \mathrm{H}_{\text {fusion }}$. If pure solid BeF2 separates upon cooling the $\mathrm{LiF}_{\mathrm{H}}-\mathrm{BeF}_{2}$ system, the relation between $a_{\mathrm{BeF}_{2}}$ and the freezing temperature T at a given concentration $\mathrm{X}_{\mathrm{BeF}_{2}}$ in the liquid is given by
$\mathrm{d}\left(\ln \mathrm{a}_{\mathrm{BeF}_{2}}\right)=\mathrm{d} \ln \left(\mathrm{X}_{\mathrm{BeF}_{2}} \gamma_{\mathrm{BeF}_{2}}\right)=\left(\Delta \mathrm{H}_{\text {fusion }} / \mathrm{RT}^{2}\right) \mathrm{dT} \quad$.
If $\Delta H_{\text {fusion }}$ is independent of $T$, then
In $\left(\mathrm{X}_{\mathrm{BeF}_{2}} \gamma_{\mathrm{BeF}_{2}}\right)=-\left(\Delta \mathrm{H}_{\text {fusion }} / \mathrm{R}\right)\left(1 / \mathrm{T}-1 / \mathrm{T}^{\circ}\right)$
with $T_{0}$ as the melting point of pure BeF2. The values of $T$ for various compositions $\mathrm{X}_{\mathrm{BeF}_{2}}$ were tabulated from the published phase diagram. ${ }^{2}$ The values of $\gamma_{\mathrm{BeF}_{2}}$ were calculated for the specified temperatures and compositions from the derived expression given earlier. A plot of
$\log \left(\mathrm{X}_{\mathrm{BeFF}_{2}} \gamma_{\mathrm{BeF}_{2}}\right)$ vs $1 / T$
is given in Figure 22. The slope of this correlation leads to a value
of $11 \pm 3 \mathrm{kcal} / \mathrm{mole}$ for $\Delta H_{\text {fusion }}$. The other lines presented in the figure include: the line obtained if $\Delta \mathrm{H}_{\text {fusion }}=1.6 \mathrm{kcal} / \mathrm{mole}$; the line obtained if $\gamma_{\mathrm{BeF}_{2}}=1$ (i.e., $\log X_{B e F 2}$ vs $I / T$ ); the line obtained if $\Delta H_{\text {fusion }}=$ $7.5 \mathrm{kcal} / \mathrm{mole}$.

The value of $1.6 \mathrm{kcal} /$ mole for $\Delta H_{\text {fusion }}$ was included for comparison because this value was recently reported ${ }^{57}$ from comparison of $\Delta \mathrm{H}_{\text {subl }}$ with $\Delta H_{\text {vap }}$. Both measurements were from the variation of vapor pressures with temperature over solid and liquid, respectively. One discrepancy in these data, which is not mentioned in the article, is that the vapor pressures reported for the solid near the melting point are greater than the extrapolated vapor pressures of the liquid by a factor of three. The fact that the reported vapor pressures for the solid and liquid do not intersect even near the melting point is indicative of a systematic error in one or the other sets of measurements since both sets seem internally consistent.

The value of $7.5 \mathrm{kcal} / \mathrm{mole}$ for $\Delta H_{\text {fusion }}$ was included for comparison because this is the value obtained if $\Delta H_{\text {fusion }}$ is determined to be the difference between $\Delta H_{f}^{\circ}$ of $\mathrm{BeF}_{2}(\underline{1})$ calculated here and $\Delta H_{f}^{\circ}$ of $\mathrm{BeF}_{2}$ (s) reported in JANAF. ${ }^{4}$ The $\triangle \mathrm{H}_{\mathrm{f}}{ }^{\mathrm{O}}$ of $\mathrm{BeF}_{2}(\mathrm{~s})$ is based on the heat of solution measurements on BeO and $\mathrm{BeF}_{2}$ in aqueous HF by Kolesov, et al. ${ }^{58}$ Since there is some question regarding the accuracy of the reported results, the value of $\Delta H_{\text {fusion }}$ is about $7.5 \pm 6 \mathrm{kcal} / \mathrm{mole}$. Although the present results do not definitely establish the value of $\Delta \mathrm{H}_{\text {fusion }}$ of $\mathrm{BeF}_{2}(\mathrm{~s})$, they do tend to support the value of $12 \mathrm{kcal} / \mathrm{mole}$ reported in JANAF rather than that of 2 kcal/mole used in the JANAF tabulation or the more recently reported value of $1.6 \mathrm{kcal} / \mathrm{mole}$.

Fig. 22. Heat of Fusion of $\mathrm{BeF}_{2}$ from Activities at Freezing Temperatures.

The values of $Q_{A}$ reported in Tables 3 and 4 were correlated with respect to temperature and composition. Visual inspection indicated that the values exhibited linear dependence on both temperature and composition. The general equation for the correlation was obtained in the following manner:
(1) The values at each temperature were grouped to determine the slope of the line
$\log Q_{A}=($ slope $) X_{\mathrm{BeF}_{2}}+$ constant. The least-square slopes a.t the five experimental temperatures were as follows:

| Temp $\left({ }^{\circ} \mathrm{C}\right)$ |  | Slope |  |
| :---: | :---: | :---: | :---: |
|  |  | No. of Values |  |
| 500 |  | $2.695 \pm 0.473$ |  |
| 50 |  | $2.480 \pm 0.357$ |  |
| 600 |  | $3.123 \pm 0.174$ |  |
| 650 |  | $2.847 \pm 0.207$ |  |
| 700 |  | $2.775 \pm 0.175$ | 16 |
|  |  | 20 |  |

(2) Using weights equal to the number of data points for each line, the average slope was determined to be 2.843. All of the values agree with this slope within the quoted standard deviations except the value at $600^{\circ}$ which is slightly larger.
(3) With the slope of all lines set at 2.843 , the value of $\log Q_{A}$ at the composition intercept $\left(\mathrm{X}_{\mathrm{BeF}_{2}}=0\right)$ was determined at each temperature to give best fit to data as shown below:

| Temp $\left({ }^{\circ} \mathrm{C}\right)$ | $\log Q_{A}$ | Temp ( ${ }^{\circ} \mathrm{C}$ ) | $\log Q_{A}$ |
| :---: | :---: | :---: | :---: |
| 500 | -3.138 | 650 | -2.757 |
| 550 | -3.056 | 700 | -2.638 |
| 600 | -2.893 |  |  |

(4) These end values were used to calculate the function of $\log Q_{A}$ vs $I / T$, which is $\log Q_{A}=-2085(1 / T)-0.503$. Thus, the best smoothed values for $Q_{A}$ over the experimental range are given by
$\log Q_{A}=2.843 X_{\mathrm{BeF}_{2}}-2085(I / T)-0.503 \cdot$
The observed values of $Q_{A}$ and the calculated values based on the above function are shown in Figure 23. Since the data at the various temperatures overlap, the coordinates are specified for each line independently. The standard deviations of the points are not shown in the figure, but most points agree within the quoted standard deviations in Table 3. The values determined in BeO-saturated melts are shown by closed symbols and those in unsaturated melts by open symbols.

The concentration of hydroxide present at equilibrium for known partial pressures of HF and $\mathrm{H}_{2} \mathrm{O}$ above a melt of known composition could be calculated using the relationship for $Q_{A}$,
$Q_{\mathrm{A}}=\left(\mathrm{P}_{\left.\mathrm{HF} / \mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}\right)\left[\mathrm{OH}^{-}\right]=\text {mole } / \mathrm{kg}, ~}^{\text {, }}\right.$
derived from the reaction
$\mathrm{H}_{2} \mathrm{O}(\mathrm{g})+\mathrm{F}^{-}(\mathrm{soln}) \rightleftharpoons \mathrm{HF}(\mathrm{g})+\mathrm{OH}^{-}(\mathrm{soln}) \quad$.
Other equilibria involving hydroxide were also introduced in Chapter
I. One reaction is
$\mathrm{H}_{2} \mathrm{O}(\mathrm{g})+\mathrm{O}^{2-}(\mathrm{soln}) \rightleftharpoons 2 \mathrm{OH}^{-}(\mathrm{soln})$
from which
$Q_{B}=\left[\mathrm{OH}^{-}\right]^{2} / \mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}=\left(Q_{A}\right)^{2} / \mathrm{Q}$
for a Beo-saturated melt. Since expressions for both $Q$ and $Q_{A}$ are known, the values of $Q_{B}$ can be derived. If the equation given earlier for $\log \left(Q / X_{\mathrm{BeF}_{2}}\right)$ is rearranged in terms of $X_{\mathrm{BeF}_{2}}$ rather than $X_{\mathrm{LiF}}$, the following equation is obtained

$$
\begin{aligned}
\log \left(Q / X_{\mathrm{BeF}_{2}}\right)= & -0.940-4596(1 / \mathrm{T})+[35.00-10168(1 / \mathrm{T})] \mathrm{X}_{\mathrm{BeF}_{2}} \\
& +[-68.14+26132(1 / \mathrm{T})] \mathrm{X}_{\mathrm{BeF}_{2}}+[50.64-21048(1 / \mathrm{T})] \mathrm{X}^{3} \mathrm{BeF}_{2} \\
& +[-12.66+5262(1 / \mathrm{T})] \mathrm{X}_{\mathrm{BeF}_{2}} .
\end{aligned}
$$

If this equation is combined with the expression for $Q_{A}$, the following holds:

$$
\begin{aligned}
\log Q_{B}= & 2 \log Q_{A}-\log Q=-0.066+426(1 / T)+[-29.31+10168(1 / T)] X_{\mathrm{BeF}_{2}} \\
& +[68.14-26132(1 / T)] X_{B e F_{2}}+[-50.64+21048(1 / T)] X_{B_{B e F_{2}}} \\
& +[12.66-5262(1 / T)] X_{\mathrm{BeF}_{2}}-\log X_{\mathrm{BeF}_{2}}
\end{aligned}
$$

The parameters of the equation
$\log Q_{B}=\operatorname{slope}(1 / T)+$ constant
are tabulated below for various experimental compositions:

| $\mathrm{X}_{\mathrm{BeF} 2}$ | Slope | Constant | $\mathrm{X}_{\mathrm{BeF}_{2}}$ | Slope | Constant |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0.30 | 1649 | -3.367 | 0.60 | 983 | -2.197 |
| 0.333 | 1629 | -3.513 | 0.70 | 695 | -1.370 |
| 0.40 | 1524 | -3.415 | 0.80 | 456 | -0.571 |
| 0.50 | 1279 | -2.925 |  |  |  |

Another reaction involving hydroxide is
$\mathrm{HF}(\mathrm{g})+\mathrm{O}^{2-}(\mathrm{soln}) \rightleftharpoons \mathrm{OH}^{-}(\mathrm{soln})+\mathrm{F}^{-}(\mathrm{soln})$
from which
$Q_{C}=\left[\mathrm{OH}^{-}\right] / P_{H F}=Q_{A} / Q$ for a BeO-saturated melt.
Therefore,

$$
\begin{aligned}
\log Q_{C}= & \log Q_{A}-\log Q=0.437+2511(1 / T)+[-32.16+10168(1 / T)] X_{\mathrm{BeF}_{2}} \\
& +[68.14-26132(1 / T)] X_{\mathrm{BeF}_{2}}+[-50.64+21048(1 / T)] X_{\mathrm{BeF}_{2}} \\
& +[12.66-5262(1 / T)] X_{\mathrm{BeF}_{2}}-\log X_{\mathrm{BeF}_{2}} .
\end{aligned}
$$

The parameters of the equation
$\log Q_{C}=$ slope $(1 / T)+$ constant
are tabulated below for various experimental compositions:

| $\mathrm{X}_{\mathrm{BeF}_{2}}$ | Slope | Constant | $\mathrm{X}_{\mathrm{BeF}_{2}}$ | Slope | Constant |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0.30 | 3734 | -3.819 | 0.60 | 3068 | -3.404 |
| 0.333 | 3714 | -3.960 | 0.70 | 2780 | -2.862 |
| 0.40 | 3609 | -4.052 | 0.80 | 2541 | -2.348 |
| 0.50 | 3364 | -3.847 |  |  |  |

If the above functions are used to evaluate equilibrium quotients for $0.333 \mathrm{BeF}_{2}$, the values obtained and $\Delta \mathrm{H}_{r}$ based on integration of the van't Hoff equation are given below:

| Equilibrium Quotients | Q at $800^{\circ} \mathrm{K}$ | Q at $1000^{\circ} \mathrm{K}$ | $\begin{gathered} \Delta H_{1} \\ \text { (kcal/mole) } \end{gathered}$ |
| :---: | :---: | :---: | :---: |
| $Q_{\text {A }}$ | $6.90 \times 10^{-3}$ | $2.29 \times 10^{-2}$ | 9.5 |
| $Q_{B}$ | $3.33 \times 10^{-2}$ | $1.30 \times 10^{-2}$ | -7.5 |
| ${ }^{\text {Q }}$ C | 4.80 | $5.70 \times 10^{-1}$ | -17.0 |

Each of these equilibrium quotients is in terms of moles of hydroxide per kilogram of melt due to experimental expediency, but they could be converted to the mole fraction scale by dividing each by moles of solvent per kilogram of melt. This conversion would not affect the $\Delta H_{r}$ values. The above values of equilibrium quotients involving hydroxide may not provide enough information to establish the complete nature of hydroxide in the LiF-BeF2 system,
but they do allow quantitative prediction of the extent of conversion of oxide to hydroxide, which is the principal controlling step in the removal of oxide by HF-sparging.

Fig. 23. Correlation of $\log Q_{A}$ as a Function of Composition and Temperature.

## Correlation of $Q_{0}$

The values of $Q_{0}$ reported in Table 4 were correlated as a function of temperature at each composition. The parameters of the equation $\log Q_{0}=\operatorname{slope}(I / T)+$ constant
are given below:

| $\mathrm{X}_{\mathrm{BeF}_{2}}$ | slope $\pm \sigma$ |  | constant $\pm \sigma$ |
| :--- | :--- | :--- | :--- |
| 0.273 | $-8158 \pm 500$ |  | No. of Points |
| $0.333 \pm 0.549$ |  | 5 |  |
| 0.400 | $-8637 \pm 349$ | $5.673 \pm 0.401$ | 24 |
| $0.9032 \pm 706$ | $7.026 \pm 0.812$ | 4 |  |

The values of $Q_{0}$ and the corresponding correlations as a function of temperature are shown in Figure 24. Since the two values for $0.60 \mathrm{BeF}_{2}$ would not yield a line with slope or intercept similar to the others, a line was drawn parallel to the line at $0.40 \mathrm{BeF}_{2}$ so as to be equidistant between the two values at $0.60 \mathrm{BeF}_{2}$.

Measurement of $Q_{0}$ at high $\mathrm{BeF}_{2}$ compositions is limited because the rate of change in $P_{H F}$ and $\mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}$ with respect to $W$ approaches the precision of measurements of the low $\mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}$ and high $\mathrm{P}_{\mathrm{HF}}$ encountered. Although additional experiments were performed on $0.60 \mathrm{BeF}_{2}$, convergence in the solution of equations to obtain $Q_{0}, Q_{A}, r_{0}$, and $s_{0}$ was not reached due to the experimental limitation mentioned above.

The data on unsaturated melts were neither extensive nor precise enough to permit a meaningful correlation with respect to melt composition. However, the solubility of BeO could be determined by comparison of these measurements with those of Be0-saturated melts.

As described in Chapter I,
$Q_{\mathrm{O}}=\left(\mathrm{P}_{\mathrm{HF}}\right)^{2}\left[\mathrm{O}^{2-}\right] / \mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}$
and since for a BeO-saturated melt
$\left(P_{H F}\right)^{2} / P_{H_{2} \mathrm{O}}=Q$,
$\left[0^{2-}\right]_{\text {sat }}=Q_{0} / Q$.
The value of $Q$ at $B e O$ saturation was established in the earlier work. Division of $Q_{0}$ by $Q$ for the same melt composition and temperature would provide the concentration of oxide at saturation.

The values of Q needed to determine BeO solubility are given by the following parameters for the equation
$\log Q=\operatorname{slope}(1 / T)+$ constant $:$

| $\mathrm{X}_{\mathrm{BeF}_{2}}$ | Slope | Constant |
| :---: | :---: | :---: |
| 0.273 | -5900 | 4.150 |
| 0.333 | -5674 | 4.233 |
| 0.400 | - 5565 | 4.528 |
| 0.600 | -5274 | 4.745 |

The solubilities in moles per kilogram of oxide in the various experiments, as determined from $Q_{0} / Q$ using observed $Q_{0}$ values and smoothed $Q$ values from the above relation, are given in Table 8. Since
$\left[0^{2-}\right]=Q_{0} / Q$,
$\log \left[0^{2-}\right]=\log Q_{0}-\log Q$,
and as both $\log Q_{O}$ and $\log Q$ show linear dependence with $(I / T), \log \left[0^{2-}\right]$ should also show linear dependence. Combination of the parameters for $Q_{0}$ and $Q$ leads to
$\log \left[0^{2-}\right]=\operatorname{slope}(I / T)+$ constant $:$

| $\frac{X_{\text {BeF } 2}}{}$ |  | Slope |  |
| :--- | :--- | :--- | :--- |
|  |  |  | Constant |
|  |  | -2258 |  |
| 0.333 |  | -2963 |  |
| 0.641 |  |  |  |
| 0.400 | -3467 |  | 2.498 |

Each of the observed solubilities is shown in Figure 25 along with the calculated expressions for the three compositions tabulated above.

Since many more experiments were performed on $0.333 \mathrm{BeF}_{2}$, the range of measured solubilities at each temperature provides a rough measure of just how well these are known. A clear trend of solubility with temperature is shown:

| $500^{\circ} \mathrm{C}$ | $(2.5-6.0) \times 10^{-3} \mathrm{moles} / \mathrm{kg}$ |
| :--- | :--- |
| 600 | $(7.2-11.8) \times 10^{-3}$ |
| 700 | $(2.3-3.8) \times 10^{-2}$ |

The other values indicate that BeO solubility may be increasing slightly with $\mathrm{BeF}_{2}$, but the increase is not very great.

Table 8. Solubility of BeO in Molten LiF-BeF2 System

| $\mathrm{X}_{\mathrm{BeF}_{2}}$ | $\left.\mathrm{T}^{\mathrm{T}} \mathrm{C} \mathrm{C}\right)$ | Run No. | $\begin{aligned} & {\left[0^{2-}\right]_{\text {sat }}} \\ & (\text { mole } / \mathrm{kg}) \end{aligned}$ | $\mathrm{X}_{\mathrm{BeF}}^{2}$ | $\begin{aligned} & \text { Temp } \\ & \left({ }^{\circ} \mathrm{C}\right) \end{aligned}$ | Run No. | $\begin{aligned} & {\left[0^{2-}\right]_{\mathrm{sat}}} \\ & (\mathrm{~mole} / \mathrm{kg}) \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0.273 | 600 | 529 | $1.30 \times 10^{-2}$ | 0.333 | 600 | 309 | $1.16 \times 10^{-2}$ |
| 0.273 | 600 | 539 | $1.04 \times 10^{-2}$ | 0.333 | 600 | 310 | $8.70 \times 10^{-3}$ |
| 0.273 | 650 | 535 | $1.46 \times 10^{-2}$ | 0.333 | 650 | 319 | $2.14 \times 10^{-2}$ |
| 0.273 | 650 | 537 | $1.48 \times 10^{-2}$ | 0.333 | 650 | 501 | $1.68 \times 10^{-2}$ |
| 0.273 | 700 | 533 | $2.13 \times 10^{-2}$ | 0.333 | 650 | 513 | $2.08 \times 10^{-2}$ |
| 0.333 | 500 | 313 | $6.67 \times 10^{-3}$ | 0.333 | 650 | 514 | $8.16 \times 10^{-3}$ |
| 0.333 | 500 | 314 | $2.53 \times 10^{-3}$ | 0.333 | 651 | 527 | $1.98 \times 10^{-2}$ |
| 0.333 | 500 | 503 | $5.72 \times 10^{-3}$ | 0.333 | 700 | 307 | $2.61 \times 10^{-2}$ |
| 0.333 | 544 | 509 | $5.85 \times 10^{-3}$ | 0.333 | 700 | 311 | $3.78 \times 10^{-2}$ |
| 0.333 | 550 | 315 | $7.25 \times 10^{-3}$ | 0.333 | 700 | 523 | $2.77 \times 10^{-2}$ |
| 0.333 | 550 | 316 | $5.09 \times 10^{-3}$ | 0.333 | 700 | 524 | $2.30 \times 10^{-2}$ |
| 0.333 | 550 | 511 | $8.45 \times 10^{-3}$ | 0.400 | 550 | 619 | $2.53 \times 10^{-2}$ |
| 0.333 | 550 | 525 | $1.17 \times 10^{-2}$ | 0.400 | 550 | 625 | $1.56 \times 10^{-2}$ |
| 0.333 | 600 | 301 | $9.47 \times 10^{-3}$ | 0.400 | 604 | 621 | $3.23 \times 10^{-2}$ |
| 0.333 | 600 | 302 | $7.18 \times 10^{-3}$ | 0.400 | 702 | 627 | $9.02 \times 10^{-2}$ |
| 0.333 | 600 | 303 | $1.18 \times 10^{-2}$ | 0.600 | 500 | 607 | $2.39 \times 10^{-2}$ |
| 0.333 | 600 | 305 | $1.11 \times 10^{-2}$ | 0.600 | 600 | 611 | $1.78 \times 10^{-2}$ |
| 0.333 | 600 | 306 | $7.23 \times 10^{-3}$ |  |  |  |  |

Fig. 24. Correlation of $\log Q_{0}$ as a Function of Temperature for Various Melt Compositions.

Fig. 25. Solubility of BeO as a Function of Temperature for Various Melt Compositions.

These studies of equilibria between $\mathrm{HF}, \mathrm{H}_{2} \mathrm{O}$, and molten LiF-BeF2 had a twofold purpose: (I) to determine as much as possible about the thermodynamics of the LiF-BeF2 system, and (2) to determine as much as possible about the oxide chemistry of the system.

The thermodynamic activities of LiF and BeF2 were determined as a function of temperature and composition. The major characteristics of the system include:
(1) Positive deviations from ideality at high $\mathrm{BeF}_{2}$ concentrations.
(2) Increasing positive deviations of the activity with temperature indicating the probability of a miscibility gap near $700^{\circ} \mathrm{C}$.
(3) Combination of activities with previously published phase diagram indicate a higher value for $\Delta \mathrm{H}_{\text {fusion }}$ of BeF 2 than currently used in thermodynamic compilations.
(4) Activities determined with BeO present are in agreement with limited previous data.

Extrapolation of data to pure liquid $\mathrm{BeF}_{2}$, which is inaccessible experimentally because of high viscosity, provides a means of determining thermodynamic properties of $\mathrm{BeF}_{2}(1)$.

The equilibria between $\mathrm{H}_{2} \mathrm{O}$, HF , and dissolved hydroxide were studied by estimating, from material balance calculations on the gas phase, the amount of $\mathrm{OH}^{-}$formed in or removed from the melt upon reaction. The results from measurements on both BeO-saturated and unsaturated melts were consistent. The results indicate that significant amounts of hydroxide were formed in the presence of 0.01 atm HF , but $\mathrm{OH}^{-}$could not exist in the absence of HF and $\mathrm{H}_{2} \mathrm{O}$.

The equilibria between $\mathrm{H}_{2} \mathrm{O}, \mathrm{HF}$, and dissolved oxide were also evaluated with melts not saturated with BeO. The solubility of BeO was estimated by combination of these results with those for BeO-saturated melts.

These results suggest methods to attack at least two allied problems:
(1) Determination of thermodynamic activities of other fluorides dissolved in the LiF-BeF2 system; and
(2) Determination of the amount of oxide in fluoride melts.

The procedure used here to determine activities of BeO-saturated melts could be applied to melts saturated with other sparingly soluble oxides. Variation in $Q$ with amount of corresponding fluoride dissolved in melt would provide information necessary to calculate change in activities.

The experiments performed here on unsaturated melts required determination of the concentration of oxide present at the start of an experiment in addition to the equilibrium quotients. If oxide analyses were required on similar melts, the equilibrium quotients could be evaluated and treated as fixed parameters, thus the variation in effluent $\mathrm{P}_{\mathrm{HF}}$ and $\mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}$ to a small value of $W$ (about 1.0 ) could be used to calculate the amount of oxide in the sample prior to treatment. In principle, this should work no matter whether oxide were being added or removed. The presence of saturating solid oxide would complicate the analysis, but the total amount of oxide present could be determined by treatment with anhydrous HF and measurement of the evolved $\mathrm{H}_{2} \mathrm{O}$.

APPENDIX A
Partial Pressures from Studies on BeO-Saturated Melts

The experiments are arranged according to a three digit "Run No." which indicates chronological order. There are three series (100, 200, 400) included. A brief history of each series is given in Chapter III. The information provided for each experiment includes:

Run No.
Composition of melt (expressed as mole fraction $\mathrm{BeF}_{2}$ )
Temperature of melt, ${ }^{\circ} \mathrm{C}$
w = weight of melt, kg
$T=$ temperature of wet-test meter, ${ }^{\circ} \mathrm{K}$
$a=$ influent $P_{H F}, \operatorname{atm} \times 10^{3}$
$c=$ influent $\mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}$, atm $\times 10^{3}$
The effluent partial pressures, $\mathrm{P}_{\mathrm{HF}}=\mathrm{x}$ and $\mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}=\mathrm{y}$, are tabulated (atm $\times 10^{3}$ ) with the corresponding initial and final values of $W(V / w R T)$. Note that the use of W allows consistent comparison of experiments independent of the weight of melt or temperature of gas-measurement. The equilibrium quotients evaluated from each experiment are presented in Table 3.

Run No. 101

APPENDIX B
Partial Pressures from Studies on Unsaturated (with respect to BeO ) Melts

The experiments are arranged according to a three digit "Run No." which indicates chronological order. There are three series $(300,500$, 600) included. A brief history of each series is given in Chapter III. The information provided for each experiment includes:

Run No.
Composition of melt (expressed as mole fraction $\mathrm{BeF}_{2}$ )
Temperature of melt, ${ }^{\circ} \mathrm{C}$
$\mathrm{w}=\mathrm{weight}$ of melt, kg
$T=$ temperature of wet-test meter, ${ }^{\circ} \mathrm{K}$
$a+b W=$ influent $P_{H F}$, atm $\times 10^{3}$
$c+d W=$ influent $P_{H_{2} \mathrm{O}}, \operatorname{atm} \times 10^{3}$
The effluent partial pressures, $\mathrm{P}_{\mathrm{HF}}=\mathrm{x}$ and $\mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}=\mathrm{y}$, are tabulated (atm $\times 10^{3}$ ) with the corresponding initial and final values of W . Note that the use of $W$ allows consistent comparison of experiments independent of the weight of melt or temperature of gas-measurement. The equilibrium quotients evaluated from each experiment are presented in table 4.

Run No. 301
$0.333 \mathrm{BeF}_{2}$ at $600^{\circ} \mathrm{C}, \mathrm{w}=0.500, \mathrm{~T}=299^{\circ} \mathrm{K}, \mathrm{a}=3.68, \mathrm{c}=11.00$

APPENDIX C

Glossary
a (or a $+b W$ ) - influent partial pressure of $H F$
$A-(a+2 c)$
$\mathrm{a}_{\mathrm{BeF}_{2}}$ - thermodynamic activity of $\mathrm{BeF}_{2}$
$\alpha, \beta$ - parameters expressing the variation in $\gamma_{\mathrm{BeF}_{2}}$ with composition at
a. specified temperature according to the equation
$\log \gamma_{\mathrm{BeF}_{2}}=\alpha X_{\mathrm{LiF}}^{2}+\beta X_{\mathrm{LiF}}^{4}$
$c$ (or $c+d W$ ) - influent partial pressure of $\mathrm{H}_{2} \mathrm{O}$
C - integration constants
$\Delta C_{p}$ - heat capacity change at constant pressure
$f-$ correction factor $=\frac{P_{W}-(x+y)}{P_{W}-P_{W}}$
$\Delta F_{r}$ - free energy of reaction
$\gamma_{\mathrm{BeF} 2}-$ activity coefficient of $\mathrm{BeF}_{2}=\mathrm{a}_{\mathrm{BeF}_{2}} / \mathrm{X}_{\mathrm{BeF} 2}$
$\Delta H_{f}{ }_{f}$ - standard heat of formation
$\Delta H_{\text {fusion }}$ - heat of fusion
$\Delta H_{r}$ - heat of reaction
$\Delta H_{\text {sub }}$ - heat of sublimation
$\Delta H_{v a p}$ - heat of vaporization
$\overline{\mathrm{H}}_{\mathrm{BeF} 2}$ - partial molal heat content of $\mathrm{BeF}_{2}$ in solution
$\mathrm{H}_{\mathrm{BeF}_{2}}^{\mathrm{O}}$ - partial molal heat content of pure liquid $\mathrm{BeF}_{2}$
K - thermodynamic equilibrium constant
$K_{a}-X^{2} / \mathrm{ya}_{\mathrm{BeF}_{2}}=\mathrm{Q} / \mathrm{a}_{\mathrm{BeF}_{2}}$
$k, 1, m$ - parameters used in correlation of $Q$ as a function of melt composition according to the equation

$$
\log \left(Q / X_{\mathrm{BeF}_{2}}\right)=k+1\left(X_{\mathrm{LiF}}\right)^{2}+m\left(X_{\mathrm{LiF}}\right)^{4}
$$

$k^{\circ}, 1^{\circ}, \mathrm{m}^{\circ}$ - temperature independent portions of k , 1 , and m , respectively
$k^{\prime}, l^{\prime}, \mathrm{m}^{\prime}$ - temperature dependent portions of $\mathrm{k}, \mathrm{l}$, and m , respectively
$\mathrm{n}_{\mathrm{HF}}$ and $\mathrm{n}_{\mathrm{H}_{2} \mathrm{O}}$ - moles of HF and $\mathrm{H}_{2} \mathrm{O}$ as measured at $\mathrm{T}_{\mathrm{W}}, \mathrm{P}_{\mathrm{W}}$
$P_{H F}$ and $\mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}$ - partial pressures of HF and $\mathrm{H}_{2} \mathrm{O}$, respectively.
$p_{w}$ - vapor pressure of water at $T_{W}$
$P_{W}$ - total pressure at wet-test meter
$P_{1}$ - partial pressure of HF or $\mathrm{H}_{2} \mathrm{O}$ leaving melt
$\mathrm{P}_{2}$ - measured partial pressure of HF or $\mathrm{H}_{2} \mathrm{O}$
Q - $x^{2} / y$ for Beo saturated melt
$Q_{A}-x s / y$
$Q_{b}-s^{2} / y r=\left(Q_{A}\right)^{2} / Q_{0}$
$Q_{B}-s^{2} / y=\left(Q_{A}\right)^{2 / Q}$
$Q_{C}-s / x r=Q_{A} / Q_{O}$
$Q_{C}-s / x=Q_{A} / Q$
$Q_{0}-x^{2} r / y$
$r$ - $\left[0^{2 "}\right]$ - oxide concentration in moles per kilogram of melt
s - [ $\mathrm{OH}^{-}$] - hydroxide concentration in moles per kilogram of melt
$r_{0}$ and $s_{0}$ - values of $r$ and $s$ at $W=0$ in unsaturated experiments
$S^{\circ}$ - standard entropy at specified temperature
$\Delta S_{r}$ - entropy of reaction
$\sigma-$ standard deviation
t - degrees Centigrade (generally used to indicate melt temperatures)
T - degrees Kelvin (used to indicate wet-test meter temperatures)
$T_{W}$ - temperature of wet-test meter, ${ }^{\circ} \mathrm{K}$
$\mu_{\mathrm{BeF}_{2}}^{\mathrm{E}}$ - excess chemical potential of $\mathrm{BeF}_{2}$
$V_{a}$ - volume of dry carrier gas going through system measured at $T_{W}, P_{W}$
$V_{b}$ - volume of gas entering titration assembly at $T_{W}, P_{W}$
$V_{m}$ - volume of gas space above the melt
$V_{W}$ - volume of gas through melt measured at $T_{W}, P_{W}$ (liters)
dV - increment of gas flowing through system as measured at $T_{w}, P_{W}$
w - weight of melt (kg)
$\mathrm{W}-\mathrm{V} / \mathrm{wRT}_{\mathrm{W}}$ (mole $\mathrm{kg}^{-1} \mathrm{~atm}^{-1}$ )
$X_{\mathrm{BeF}_{2}}$ - mole fraction $\mathrm{BeF}_{2}$
$x$ - effluent partial pressure of $H F$
$y$ - effluent partial pressure of $\mathrm{H}_{2} \mathrm{O}$

INTERNAL DISTRIBUTION

EXTHRNAL DISTRIBUITION
69. Research and Development Division, ORO

70-84. Division of Technical Information
85. F. A. Anderson, Chemical Engineering Dept., University of Miss., University, Mississippi
86. M. J. Blander, North American Aviation Science Center, 8437 Fallbrook Avenue, Canoga Park, California
87. A. Büchler, Arthur D. Little, Inc., 30 Memorial Drive, Cambridge 42, Massachusetts
88. S. F. Clark, University of Mississippi, University, Mississippi
89. P.A.D. deMaine, University of California, Santa Barbara, Calif.
90. G. Dirian, Commissariat a 1'Energie Atomique (CEN Saclay) 69, Rue de Varenne, Paris, France
91. C. F. Dodson, Western Carolina College, Cullowhee, North Carolina.
92. F. R. Duke, Texas A and M College, College Station, Texas
93. J. E. Eorgan, Kawecki Chemical Co., Boyertown, Pennsylvania
94. H. Flood, Institute of Silicate Science, Norwegian Institute of Technology, Trondheim, Norway
95. Tormod F申rland, The Institute of Theoretical Chemistry, Trondheim, Norway
96. R. M. Fuoss, Yale University, New Haven, Connecticut
97. M. A. Greenbaum, Rocket Power Inc., Research Laboratories, Pasadena, Califormia
98. Marwin Kemp, University of Arkansas, Fayetteville, Arkansas
99. O. J. Kleppa, Chemistry Department, University of Chicago, Chicago, Illinois
100. S. Langer, General Atomics, P.O. Box 608, San Diego, California
101. G. Long, Chemistry Dept., UKAEA, Harwell, Didcot, Berks., England
102. C. R. Masson, National Research Council of Canada, Atlantic Regional Laboratory, Halifax, Nova Scotia
103-112. A. L. Mathews, Western Carolina College, Cullowhee, North Carolina
113. D. A. Mathewes, Western Carolina College, Cullowhee, North Carolina
114. J. L. Margrave, Rice University, Houston, Texas
115. N. J. Meyer, Department of Chemistry, Bowling Green State University, Bowling Green, Ohio
116. G. Nessle, Kawecki Chemical Co., Boyertown, Pennsylvania
117. S. Pizzini, Euratom, CCR, Ispra, Italy
118. P. A. Reid, Westerm Carolina College, Cullowhee, North Carolina
119. Rustum Roy, Materials Research Laboratory, The Pennsylvania State University, University Park, Pennsylvania
120. S. D. Squibb, Asheville-Biltmore College, Asheville, North Carolina
121. B. R. Sundheim, New York Univeristy, New York, New York
122. E. L. Topol, 19806 Gilmore Street, Woodland Hills, California
123. W. J. Wallace, Muskegon College, Muskegon, Michigan
124. J. Zarzycki, Compagnie de Saint-Gobain, 52 Bd De La Villette, Paris 19e, France

[^0]:    ${ }^{a_{\text {Solid }}}$ LiF present, mole fraction $\mathrm{BeF}_{2}$ actually higher than indicated.
    ${ }^{b}$ Case $I, Q$ value specified for $Q_{A}$ determination.
