ABSTRACT

For seven molten salt mixtures:

four fuel mixtures, each containing LiF, BeF₂, ThF₄, UF₄
one flush salt, LiF-BeF₂ (66-34 mole %)
two coolant salts, NaBF₄-NaF (92-8 mole %) and single-
component NaBF₄

estimates and/or experimental values are given for the following properties:

viscosity,
thermal conductivity,
electrical conductivity,
phase transition behavior,
heat capacity,
heat of fusion,
density,
expansivity,
compressibility,
vapor pressure,
surface tension,
solubility of the gases, He, Kr, Xe, BF₃.

From the foregoing properties, the following have also been calculated and appended:

isochoric heat capacity (C_v)
sonic velocity
thermal diffusivity
kinematic viscosity
Prandtl number.

Composition of Salt Mixtures

INTRODUCTION

In this document we have compiled physical property information, either measured or estimated, on seven salt mixtures that are presently of importance in the design of advanced molten salt reactors. The primary user of this compilation will, no doubt, be the nuclear reactor engineer who requires these data for the design and development of molten salt reactors. Specialists in the chemistry of molten salts may be another audience interested in this report. We earnestly hope that all who critically examine or otherwise use these data will give us the benefit of their advice so that future versions of this document can be greatly improved.

Basis for Selecting the Salts

The choice of salt mixtures has been primarily governed by recent changes in the Molten Salt Reactor Program: (a) the combining of fissile and fertile material within the same circuit (the "single-region" concept), and (b) the testing of coolant salts which are mainly NaBF_4 .

Four mixtures have been selected for possible use as single-region fuel melts. These are:

<u>Salt Mixture</u>	<u>Composition (mole %)</u>			
	<u>LiF</u>	<u>BeF₂</u>	<u>ThF₄</u>	<u>UF₄</u>
F ₁	73	16	10.7	0.3
F ₂	72	21	6.7	0.3
F ₃	68	20	11.7	0.3
F ₄	63	25	11.7	0.3

Salts F_1 and F_3 are fuel mixtures appropriate to a prismatic configuration of the graphite moderator; the lesser concentrations of BeF_2 and ThF_4 in F_1 may be more favorable with respect to rare-earth fission product removal by reductive extraction.

Salt F_2 , containing a relatively low concentration of thorium, might be used in a reactor (e.g., with random-packed graphite spheres) where good breeding performance is not a prime consideration. Mixture F_4 , on the other hand, could contribute to improved breeder performance mainly because the higher the beryllium concentration, the greater the opportunity to increase neutrons by the $(n, 2n)$ reaction.

It is worthwhile noting that for the purposes of estimating physical properties of salts F_1 - F_4 , the effects of the small concentration of UF_4 was almost always assumed to be the same as for the corresponding increase in the ThF_4 concentration.

Although no firm decision has been reached as to the exact composition of the fuel salt for the next molten salt reactor, it is highly probable that the concentrations of LiF , BeF_2 and ThF_4 will be within the limits given for these components by the above four mixtures.

Physical property information is also provided for:

LiF-BeF_2 (66-34 mole %) symbolized as L_2B .

This mixture has been used in the MSRE as the coolant and as the flush salt for the fuel circuit. The inclusion of L_2B

in this report is justified by the good possibility that it will be a flush salt (and perhaps a coolant) in future molten salt reactors.

As intermediate coolant (in this case the fluid which transports heat from the fuel salt to the steam generators) the salts which presently appear attractive contain mostly NaBF_4 . Two such salts are considered:

<u>Coolant</u>	Composition (mole %)	
	<u>NaBF_4</u>	<u>NaF</u>
C_1	92	8
C_2	100	

The salt symbolized as C_1 is a eutectic composition which melts at 385°C (725°F). Although a lower melting fluoroborate mixture would be desirable, it is not presently clear how much and which additive will substantially depress the melting temperature. Moreover, it seems likely that lower melting fluoroborate mixtures will not be very different from C_1 ; hence mixture C_1 seems, at present, the leading candidate for the next coolant to be tried in a molten salt reactor.

Another salt for which estimates are tabulated in this report is "pure" NaBF_4 , symbolized as C_2 . Since stoichiometric NaBF_4 does not exist in the molten state without a very high partial pressure of BF_3 gas, C_2 cannot be considered a practical coolant. However, estimations of the physical properties of hypothetically pure molten NaBF_4 are useful for evaluating the contributions of NaBF_4 as a component in

a salt mixture. In solution, $[\text{BF}_4]^-$ ion may be imagined to behave like a halide ion, slightly larger and more polarizable than iodide ion. By applying this analogy, several properties of C_2 were estimated from the measured properties of molten NaI .

For convenience, a list of salt compositions and their corresponding liquidus temperatures are given after the abstract (page 2) and at the end of this report (page 46).

Uncertainties Listed with the Physical Property Values

Each contributor has stated what he believes is the error associated with the experimental result or with the estimated quantity. For most cases, the uncertainty represents considerably more than either "goodness of fit" of an interpolation or internal consistency available from thermodynamics. Instead, the uncertainty may be considered as the largest probable combination of systematic and random errors associated with the value given for the property. Where the listing is a property-temperature equation, the uncertainty is for the property calculated at the temperature substituted in the equation. In properties where the number of significant figures are not justified by the specified uncertainties, the extra significant figures are given to aid the reader in judging whether a particular salt is "less than" or "greater than" another salt for the property in question.

Although the magnitudes of the uncertainties are highly intuitive and often disappointingly large, they should be

taken seriously. Each contributor, while not necessarily qualifying as "expert" in the physical property, either possesses long experience in measuring the property or has carefully (and usually critically) reviewed the literature for that property. In other words, for each property the person whose name is given is at least a very interested observer and may also be an active participant.

For Further Information ---

It is best to contact the person (or persons) listed under the property heading. The editor hopes to provide addenda to this report as newer, more reliable, data become available.

VISCOSITY

S. Cantor

Viscosity-Temperature Equation

Salt	η in Centipoise, T in $^{\circ}\text{K}$	Uncertainty
F ₁	$\eta = 0.084 \exp (4340/T)$	25%
F ₂	$\eta = 0.072 \exp (4370/T)$	25%
F ₃	$\eta = 0.077 \exp (4430/T)$	25%
F ₄	$\eta = 0.0444 \exp (5030/T)$	25%
L ₂ B	$\eta = 0.116 \exp (3755/T)$	15%
C ₁	$\eta = 0.04 \exp (3000/T)$	50%
C ₂		

Sources of Data and Methods of Estimation

Salts F₁-F₄: Estimated empirically from viscosities in the system LiF-BeF₂-UF₄ (ref. 1) and also from measurements of LiF-BeF₂-ThF₄ (71-16-13 mole %).² It was assumed that the effect of ThF₄ concentration on viscosity was the same as that observed for UF₄.

L₂B: Measured³

C₁ and C₂: The equation was derived from (a) preliminary measurements of NaBF₄,⁴ and (b) assuming that the temperature variation of viscosity for NaBF₄ is equal to that of NaI.⁵

Given the rather large uncertainty, the contribution of NaF (in C₁) to the viscosity may be considered negligible.

Discussion

Viscosities of Reactor Fuel Mixtures

From the reported viscosity measurements¹ of the system LiF-BeF₂-UF₄, two trends can be observed:

(a) for LiF concentrations of 60 mole % or greater, substitution of UF₄ for BeF₂ (at const. temp.) causes an increase in viscosity,

(b) increasing LiF from 60 to 70 mole %, at const. temp. and at const. UF₄ concentration, decreases the viscosity by, at most, a factor of 1/2; for most compositions the factor is closer to 3/4.

The data and trends observed for the system LiF-BeF₂-UF₄ can serve to predict reliably (i.e., to within 25%) the viscosities in the slightly different system, LiF-BeF₂-MF₄ (M is Th and/or U). Assuming that all single-region fuel mixtures will be restricted to the following ranges of component composition:

62 - 73 mole % LiF

15 - 30 mole % BeF₂

6 - 16 mole % MF₄ ,

then one may conclude that the predicted viscosities have a rather narrow range of values, e.g.,

at 600°C, 9 - 16 Centipoise

at 700°C, 5 - 9 Centipoise

THERMAL CONDUCTIVITY

J. W. Cooke

<u>Salt</u>	<u>Thermal Conductivity^a in watt/(cm-°C)</u>	<u>Uncertainty</u>
F ₁	0.01 ₀ ^b	≥ ± 25%
F ₂	0.01 ₁ ^b	≥ ± 25%
F ₃	0.008 ₃ ^b	≥ ± 25%
F ₄	0.007 ₀ ^b	≥ ± 25%
L ₂ B	0.010	± 10%
C ₁	0.005 ₂	± 50%
C ₂	0.005 ₁	± 50%

^a As a first approximation, the temperature dependence of thermal conductivity may be neglected. Although the thermal conductivity of molten salts does vary somewhat with temperature, uncertainties in measurements at a given temperature are usually greater than the temperature dependence over the whole range of temperature (usually an interval of 200°C).

^b Before assuming anything about the relative values of the four fuel melts, please read the caveat in the Discussion.

Sources of Data and Methods of Estimation

Salts F₁ - F₄: Estimated by means of a theoretical expression derived by Rao¹ and adapted to molten salts by Turnbull.² The expression is

$$k \text{ (in } w \text{ cm}^{-1} \text{ } ^\circ\text{C}^{-1}) = 11.9 \times 10^{-3} \frac{T_m^{1/2} \rho_m^{2/3}}{(M/n)^{7/6}}$$

where T_m = melting point (°K), ρ_m = liquid density in g cm⁻³ at T_m , M = average molar weight and n = average number of discrete

ions per molecule. Part of the expression,

$$11.9 \times 10^{-3} T_m^{1/2} \rho^{1/3} / (M/n)^{5/6} ,$$

is a good approximation to the average maximum Debye lattice frequency for single ionic salts.² It was found for eleven molten mixtures (nitrates or chlorides) that the above expression agreed with experimental results, on the average, to within 15%. For two fluoride melts, one L₂B,³ the other, LiF-BeF₂-ThF₄-UF₄ (71.2-23-5-.8 mole %),³ the theoretical expression yielded values approximately 25% less than experimental. Note that the latter is very similar in composition to F₂.

In applying the theoretical expression the liquidus temperature was substituted for T_m; in computing n, the following ions were assumed: Li⁺, F⁻, (BeF₄)²⁻, (ThF₅)⁻¹, (UF₅)⁻¹. Assumption of the more plausible ions, (ThF₇)⁻³ and (UF₇)⁻³ leads to a lower and less reliable estimated thermal conductivity. Also, 15% was added to the estimated value because of the previously noted discrepancy for the cases of the two similar fluoride mixtures.

L₂B: Measured³

C₁, C₂: Very preliminary measurement³ on C₂ agrees with the theoretical expression.

Discussion

The relative conductivities of the four fuel mixtures, F₁-F₄, are not more reliable than the absolute values. The tabulated conductivities were obtained from a theoretical

equation that was greatly extended to apply to these mixtures. The dearth of accurate experimental data prevents adequate testing of the extended theoretical expression either absolutely or relatively.

ELECTRICAL CONDUCTIVITY

G. D. Robbins

<u>Salt</u>	<u>Specific Conductivity - Temperature Equation</u>	<u>Uncertainty</u>
	κ in $(\text{ohm-cm})^{-1}$, t in $^{\circ}\text{C}$	
F ₁	$\kappa = 1.72 + 8.0 \times 10^{-3} (t-500)$	$\pm 20\%$
F ₂	$= 1.63 + 7.3 \times 10^{-3} (t-500)$	$\pm 20\%$
F ₃	$= 1.66 + 6.4 \times 10^{-3} (t-500)$	$\pm 20\%$
F ₄	$= 1.94 + 7.1 \times 10^{-3} (t-500)$	$\pm 20\%$
L ₂ B	$= 1.54 + 6.0 \times 10^{-3} (t-500)$	$\pm 10\%$
C ₁	$= 2.7 + 13 \times 10^{-3} (t-500)$	$\pm 50\%$
C ₂	$= 1.92 + 2.6 \times 10^{-3} (t-500)$	$\pm 20\%$

Sources of Data and Method of Estimation

For 6 salts κ was estimated empirically from data on related or analogous salt melts. Often the assumptions employed were not those which seemed physically most reasonable, but those which resulted in the most self-consistent correlation of the data. Therefore, estimated κ 's are believed to have relatively large uncertainties. The number of significant figures in the equations for κ vs. t are not meant to contradict the listed uncertainties, but rather are intended to show differences between salt mixtures whose conductivities are predicted to be very similar.

Salts F₁ - F₄: The following equations were employed in these estimates:

$$\Lambda_{\Theta} = \kappa_{\Theta} \cdot \frac{M_e}{\rho_{\Theta}}$$

$$\Theta = \frac{T_{\Theta} (^{\circ}\text{K})}{T_{\text{liquidus}} (^{\circ}\text{K})}$$

$$M_e = X_{\text{LiF}} M_{\text{LiF}} + \frac{1}{4} X_{\text{ThF}_4} M_{\text{ThF}_4} + \frac{1}{2} X_{\text{BeF}_2} M_{\text{BeF}_2}$$

- Λ_{Θ} = equivalent conductivity at a corresponding temperature Θ
 κ_{Θ} = specific conductivity at Θ
 ρ_{Θ} = density at Θ
 M_e = equivalent weight of a mixture
 M = formula weight of a component
 X = mole fraction
 X' = equivalent fraction

At several values of Θ smoothed curves of Λ_{Θ} vs X'_{ThF_4} were obtained from conductivities of the system LiF-ThF₄ measured by Brown and Porter.¹ Liquidus temperatures reported in references 2 and 3 were used in calculating Θ . Similar curves for LiF-BeF₂ were derived by plotting the experimental results for a single composition (66 mole % LiF)⁴ and assuming that the variation of Λ_{Θ} with X' in the LiF-BeF₂ system was equal to that in LiF-ThF₄. (For these estimates UF₄ was treated as indistinguishable from ThF₄.) The equations of κ vs. t given above were then derived by assuming that Λ_{Θ} is additive in X'_{ThF_4} and X'_{BeF_2} for a given concentration of LiF.

L₂B: Preliminary measurements.⁴

C₂: The ratio $\Lambda_{\Theta\text{NaI}}/\Lambda_{\Theta\text{KI}}$ appeared relatively constant in the range $\Theta = 1.05 - 1.20$ (data for NaI and KI from ref. 5). Assuming that $\Lambda_{\Theta\text{NaBF}_4}/\Lambda_{\Theta\text{KBF}_4} = \Lambda_{\Theta\text{NaI}}/\Lambda_{\Theta\text{KI}}$, specific conductance data of Winterhager and Werner⁶ for KBF₄ were combined with density estimates for KBF₄ and NaBF₄⁷ to obtain values of $\Lambda_{\Theta\text{NaBF}_4}$ vs. Θ (liquidus temperatures, from reference 8).

C₁: Specific conductivity data in the range 47 to 77 mole % NaBF₄ in the NaF-NaBF₄ system⁹ were combined with those calculated for pure NaBF₄ (see C₂) to interpolate κ for the composition NaBF₄-NaF (92-8 mole %). The large uncertainty listed reflects a lack of confidence in the data reported in reference 9.

Discussion

Specific conductivity is determined from resistance measurements according to the relation

$$\kappa = \frac{1}{R_{\infty}} (\ell/a)$$

where (ℓ/a) is the cell constant. For a given apparatus and set of experimental conditions, the measured value of resistance can vary with the frequency of the applied potential wave form.¹⁰ The values of κ listed above are valid for resistance extrapolated to infinite frequency (denoted as R_{∞}). Thus predicting the resistance of the melt which will be measured in a particular experimental arrangement not only requires a value for conductivity κ , but also presupposes a knowledge of the frequency dispersion characteristics of the measuring device.

solid (25-243°C)	0.23 + 6.0 x 10 ⁻⁴ t	± 6

Sources of Data and Methods of Estimation

Salts F₁ - F₄: Liquid heat capacities were estimated by assuming mole-fraction additivity and assigning 16, 24, and 44 cal mole⁻¹ °C⁻¹ for the respective contributions of LiF, BeF₂, and ThF₄. The heat capacities for the solids were estimated by assuming that (a) temperature coefficient and (b) difference in C_p between liquid and solid are the same as that measured for LiF-BeF₂-ThF₄ (72-16-12 mole %).¹

L₂B: Liquid C_p is the average of two independent sets of measurements. Hoffman² obtained 0.577 cal. g⁻¹ °C⁻¹; Douglas and Payne³ obtained 0.56 cal g⁻¹ °C⁻¹. The solid heat capacity

is that of Douglas and Payne.

C_1 : Measured¹

C_2 : Measured¹. Agrees within experimental error with that derived from C_1 by subtracting enthalpy contribution of NaF^4 assuming negligible heat of mixing between NaBF_4 and NaF .

Discussion

The values of 16 and 24 cal mole⁻¹ °C⁻¹ were chosen for the respective C_p contributions of LiF and BeF₂ because 8 cal (g-atom)⁻¹ °C⁻¹ is the average observed for alkali and alkaline earth halides.⁵ The C_p of 44 cal mole⁻¹ °C⁻¹ for the contribution of ThF₄ was assumed from the average value of 8.8 cal (g-atom)⁻¹ °C⁻¹ for lanthanide halides.⁶

The validity of using the indicated additive contributions for estimating liquid heat capacities was checked by comparing with measured values of three related salts:

<u>Salt Mixture</u>	<u>Estimated C_p</u>	<u>Measured C_p</u>	<u>References</u>
L ₂ B	0.57 cal g ⁻¹ °C ⁻¹	0.57	2, 3
LiF-BeF ₂ -ThF ₄ 72 - 16 - 12 m %	0.32 ₆	0.324	1
LiF-ThF ₄ 75 - 25 m %	0.24	0.25	7

HEAT OF FUSION

A. S. Dworkin

<u>Salt</u>	<u>ΔH_{fusion} (cal g⁻¹)</u>	<u>Uncertainty</u>
F ₁	62	± 10%
F ₂	67	± 15
F ₃	58	± 15
F ₄	63	± 15
L ₂ B	107	± 3
C ₁	31	± 2
C ₂	29	± 2
ΔH of solid transition (cal g ⁻¹)		
C ₁	14.5 (at 243°C)	± 2%
C ₂	14.7 (at 243°C)	± 2

Sources of Data and Methods of Estimation

Salts F₁ - F₄: Although there is no isothermal heat of fusion, estimations were made as if all the melting (or freezing) occurred at 500°C. The salts were treated as additive mixtures of the components, Li₂BeF₄, Li₃ThF₇, and LiF or ThF₄. Li₂BeF₄ was considered to be "formed" first from the BeF₂ present and the appropriate quantity of LiF. The remainder of the mixture was then considered to consist of Li₃ThF₇ and either LiF or ThF₄, whichever was "in excess." For example, for 1 mole of salt F₁, .16 moles of BeF₂ and .32 moles of LiF form .16 moles of Li₂BeF₄ while .11 moles of ThF₄ and the remaining .41 moles of LiF give .11 moles of Li₃ThF₇ and .08 moles of LiF. The estimation is then made on the basis of .16 moles Li₂BeF₄, .11 moles ThF₄ and .08 moles LiF.

The following heats of fusion were used in making the estimations:

Li_2BeF_4	10,600 cal mole ⁻¹	(ref. 1)
Li_3ThF_7	13,960 cal mole ⁻¹	(ref. 2)
LiF	6,470 cal mole ⁻¹	(ref. 3)
ThF_4	11,000 cal mole ⁻¹	estimated by assuming the entropy of fusion is the same as that of UF_4 (ref. 4)

L_2B : Measured.¹

C_1 and C_2 : Measured.⁵ C_2 agrees within experimental error with that calculated by subtracting the contribution of the heat of fusion of NaF ⁶ from C_1 .

Discussion

Although the assumptions used in estimating ΔH_{fusion} for salts $\text{F}_1 - \text{F}_4$ are highly intuitive, it is encouraging to note that the estimated and measured⁷ ΔH_{fusion} are respectively 57.5 and 59 cal g⁻¹ for the salt mixture $\text{LiF}-\text{BeF}_2-\text{ThF}_4$ (72-16-12 mole %).

For salts $\text{F}_1 - \text{F}_4$, to obtain the heat necessary to convert the solid at the solidus temperature to the melt at the liquidus temperature, an additional 10 to 15 cal g⁻¹ should be added to the above listed heats of fusion. For convenience in calculating the quantity of heat necessary to raise the salt from room temperature to any desired temperature, the following heat content equations (based on measurements) are included:

LiF-BeF₂-ThF₄ (72-16-12 mole %) - ref. 5

$$\text{Solid: } H_t\text{-H}_{25} \text{ (cal g}^{-1}\text{)} = -5.28 + .207t + 6.33 \times 10^{-5}t^2;$$

$$(25 - 440^\circ\text{C})$$

$$\text{Liquid: } H_t\text{-H}_{25} \text{ (cal g}^{-1}\text{)} = 11.34 + .324t \text{ (500 - 750}^\circ\text{C)}$$

LiF-BeF₂ (66-34 mole %)

$$\text{Solid: } H_t\text{-H}_{0\text{O}\text{C}} \text{ (cal g}^{-1}\text{)} = 0.3179t - 1.806 \times 10^{-4}t^2;$$

$$(0 - 472^\circ\text{C}) - \text{ref. 1}$$

$$\text{Liquid: } H_t\text{-H}_{0\text{O}\text{C}} \text{ (cal g}^{-1}\text{)} = 32.632 + 0.561t; \text{ (472 - 600}^\circ\text{C)} -$$

$$\text{ref. 1}$$

$$H_t\text{-H}_{30} \text{ (cal g}^{-1}\text{)} = 33.62 + 0.577(t-30); \text{ref. 7}$$

NaBF₄-NaF (92-8 mole %) - ref. 5

$$\text{Solid: } H_t\text{-H}_{25} \text{ (cal g}^{-1}\text{)} = -5.90 + .230t + 2.90 \times 10^{-4}t^2;$$

$$(25 - 243^\circ\text{C})$$

$$H_t\text{-H}_{25} \text{ (cal g}^{-1}\text{)} = 0.40 + .337t; \text{ (243 - 381}^\circ\text{C)}$$

$$\text{Liquid: } H_t\text{-H}_{25} \text{ (cal g}^{-1}\text{)} = 22.1 + .360t; \text{ (381 - 600}^\circ\text{C)}$$

DENSITY OF LIQUID

(S. Cantor)

<u>Salt</u>	<u>Density-Temperature Equation</u>		<u>Uncertainty</u>
	ρ (in g/cm ³)	t (in °C)	
F ₁	$\rho = 3.628 - 6.6 \times 10^{-4} t$		3%
F ₂	$= 3.153 - 5.8 \times 10^{-4} t$		3
F ₃	$= 3.687 - 6.5 \times 10^{-4} t$		3
F ₄	$= 3.644 - 6.3 \times 10^{-4} t$		3
L ₂ B	$= 2.214 - 4.2 \times 10^{-4} t$		2
C ₁	$= 2.27 - 7.4 \times 10^{-4} t$		5
C ₂	$= 2.26 - 7.4 \times 10^{-4} t$		5

Sources of Data and Methods of Estimation

Salts F₁ - F₄ - Estimated by additivity of molar volumes (see Ref. 1). The following molar volumes were used:

	<u>600°C</u>	<u>800°C</u>	<u>Ref.</u>
LiF	13.411 cm ³	14.142 cm ³	2
BeF ₂	23.6	24.4	1,3
ThF ₄ and UF ₄	46.43	47.59	2

Salt L₂B - Three experimental determinations have been reported; refs. 5 and 6 were over a wide temperature range with the densities of ref. 6 averaging 3% higher than ref. 5. Reference 4 reports densities at 649°C which vary from 1.87 to 2.02 g cm⁻³. The density-temperature equation given above

was derived from additive molar volumes; this equation yields densities that are approximately the average of the densities of refs. 5 and 6.

Salt C_1 - Preliminary pycnometric measurements.⁷

Salt C_2 - The relatively small concentration of NaF in C_1 would be expected to increase the density slightly over that for "pure" NaBF_4 . The density-temperature equation was calculated by subtracting the contribution of NaF (ref. 1) from the molar volume of C_1 .

EXPANSIVITY (VOLUME COEFFICIENT OF THERMAL EXPANSION)

S. Cantor

<u>Salt</u>	<u>Estimated Value at 600°C^a</u>	<u>Uncertainty</u>
F ₁	2.0 ₄ x 10 ⁻⁴ /°C	25%
F ₂	2.0 ₇	25
F ₃	1.9 ₇	25
F ₄	1.9 ₃	25
L ₂ B	2.1 ₄	20
C ₁	4.0	40
C ₂	4.0	40

^aFor estimating the expansivity at other temperatures, please substitute in the appropriate density-temperature equation. (see discussion below).

Sources of Data and Methods of Estimation

The expansivity is defined as

$$\alpha = \frac{1}{V} \left(\frac{\partial V}{\partial T} \right)_P$$

where V, T and P are volume, temperature and pressure. Since density is inversely proportional to volume, the expansivity is usually derived from density-temperature data:

$$\alpha = - \frac{1}{\rho} \frac{d\rho}{dT} \quad (P \text{ ordinarily one atm.})$$

Most density data for liquids are linear with and decrease with temperature, i.e.,

$$\rho = \rho_0 - a t \quad (1)$$

ρ_0 and a are constants; t is usually in degrees Celsius. Thus,

expansivity is very simply

$$\alpha = \frac{a}{\rho} \quad (2)$$

The tabulated expansivities are consistent with the corresponding density-temperature equations in the "Density of Liquid" section of this report. To calculate the expansivity for any temperature, substitute in equations (1) and (2). As a rough approximation, the expansivity is one half to one third of the temperature coefficient of density as given by the constant a in eqn. (1).

COMPRESSIBILITY (ISOTHERMAL)^a

S. Cantor

Salt	Compressibility-Temperature Equation β_T in $\text{cm}^2\text{dyne}^{-1}$, T in $^\circ\text{K}$
F ₁ F ₂ F ₃ F ₄ L ₂ B	$\beta_T = 2.3 \times 10^{-12} \exp(1.0 \times 10^{-3} T)$
C ₁ C ₂	$\beta_T = 9.0 \times 10^{-12} \exp(1.6 \times 10^{-3} T)$

The compressibilities pertain to the liquid and are all estimated; the uncertainty is a factor of 3.

^aIsothermal compressibility is a function of pressure as well as temperature. The tabulated equations are less reliable at higher pressures (>50 atm).

Methods of Estimation

Salts F₁-F₄, L₂B: Estimated empirically from the compressibility-temp. equations of LiF and Li₂SO₄ (see ref. 1).

C₁ and C₂: Assumed to be slightly more compressible than NaI (see ref. 1).

Reasonable values derived for C_p/C_v and for sonic velocities (see Appendix A of this report) lend support to these estimated compressibilities.

VAPOR PRESSURE

S. Cantor

Salt ^a	Pressure-Temperature Equation (P in torr, T in °K)	Uncertainty in Pressure
F ₁	$\log P = 8.0 - \frac{10,000}{T}$	A factor of fifty from 500-700°C
F ₂		
F ₃		
F ₄		
L ₂ B	$\log P = 9.04 - \frac{10,500}{T}$	A factor of ten from 500- 700°C
C ₁	$\log P \text{ (of BF}_3 \text{ vapor)}^b = 9.024 - \frac{5,920}{T}$	± 10% from 400-700°C
C ₂	Pressure of BF ₃ depends on amount of salt and on vapor volume (see Discussion below)	

^aIn no case is the composition of the vapor congruent with the composition of the melt.

^bThe pressures given by the equation are those in equilibrium with a melt whose composition is fixed at NaBF₄-NaF (92-8 mole %).

Sources of Data and Methods of Estimation

Salts F₁-F₄: Estimated empirically from vapor pressure data of the LiF-BeF₂ system¹ and of LiF-UF₄ (73-27 mole %).² Although the uncertainty is relatively large, please note that the vapor pressures for the 500 - 700°C temperature range are quite low (between 10⁻² and 10⁻⁵ torr).

L₂B: Estimated from data in the LiF-BeF₂ system.²

C_1 : Experimentally determined.³

Discussion - The Dissociation Pressure of NaBF_4

When NaBF_4 is thermally equilibrated at a temperature above its melting point the following dissociation occurs:

The dissociation product, NaF , dissolves in the NaBF_4 . The system described by the above equation is bivariant; thus, a constant partial pressure of BF_3 above the melt requires that the temperature and the melt composition both be constant. For reaction (1) the BF_3 pressure is related to the composition of the melt by the equation:

$$P_{\text{BF}_3} = K \frac{a_{\text{NaBF}_4}}{a_{\text{NaF}}} \quad (2)$$

where K is the equilibrium constant and a_i is activity. The temperature dependence of K has been derived from experimental data³ and is given by

$$\ln K \text{ (in atm)} = \frac{-29,800}{RT \text{ (in } ^\circ\text{K)}} + \frac{26.41}{R} \quad (3)$$

[29,800 cal and 26.41 cal ($^\circ\text{K}$)⁻¹ are the enthalpy and entropy of the reaction; R , the gas constant, is 1.98717 cal ($^\circ\text{K}$)⁻¹ (g-mole)⁻¹].

A consequence of the bivariance of the NaBF_4 - NaF system is that the equilibrium BF_3 vapor pressure is difficult to predict for melts in which the concentration of NaBF_4 is very large (>98 mole %). For these concentrations, a_{NaBF_4} is virtually unity, but a_{NaF} is very small (<0.1); hence, by

equation (2), P_{BF_3} tends to be quite high. Thus for any experiment in which crystalline NaBF_4 is encapsulated, the temperature of the sample should be kept as low as necessary or else sufficient vapor space should be included so as to permit the dissociation reaction (1) to occur.

SURFACE TENSION

J. W. Cooke, S. Cantor

Salt	Surface Tension-Temperature Equation γ in dynes/cm, t in $^{\circ}\text{C}$	Uncertainty
$\left. \begin{array}{l} F_1 \\ F_2 \\ F_3 \\ F_4 \\ L_2 B \end{array} \right\}$	$\gamma = 260 - 0.12 t$	+30, -10%
C_1	$\gamma = 130 - 0.075 t$	$\pm 30\%$
C_2	$\gamma = 120 - 0.075 t$	$\pm 25\%$

Sources of Data and Methods of Estimation

Salts F_1 - F_4 , $L_2 B$: Estimated primarily from maximum bubble pressure measurements on $\text{NaF}-\text{BeF}_2$,¹ $\text{LiF}-\text{BeF}_2-\text{ThF}_4-\text{UF}_4$,² LiF ,³ and ThF_4 ³ melts. Measurements at one temp. (480°C) of $\text{LiF}-\text{BeF}_2$ (63-37 mole %)⁴ by the ring method tends to support bubble pressure values. Sessile drop measurements⁵ on $L_2 B$, on $\text{LiF}-\text{BeF}_2-\text{ZrF}_4-\text{ThF}_4-\text{UF}_4$ (70-23-5-1-1), and on other fluoride melts would have led to higher predicted values. The higher uncertainty in the positive direction expresses the possibility that the sessile drop investigations might have yielded more accurate surface tensions.

Salt C_1 and C_2 : Assumed that NaBF_4 (C_2) and NaI ⁶ exhibit (a) equal surface tensions at their melting points, (b) equal temperature coefficients of surface tension. Then

it was assumed that NaF in C_1 increased the surface tension over that of C_2 by 10%.

SOLUBILITY OF HELIUM, KRYPTON, AND XENON

G. M. Watson

Unit of solubility - $\underline{10^{-8}}$ moles of inert gas per (cm³ melt-atm).

<u>Salt</u>	<u>Temperature (°C)</u>	<u>He</u>	<u>Kr</u>	<u>Xe</u>
F ₁ F ₂ F ₃ F ₄ L ₂ B	500	6.6	0.13	0.03
	600	10.6	0.55	0.17
	700	15.1	1.7	0.67
	800	20.1	4.4	2.0
C ₁	500	44	20	12
	600	52	40	28
	700	60	69	54
	800	66	106	91
C ₂	500	52	32	21
	600	61	61	46
	700	69	100	84
	800	75	148	136

All solubilities are estimated; the uncertainty is a factor of ten or greater.

Sources of Data and Methods of Estimation

Solubilities of noble gases were estimated by a method originally proposed by Blander et al.¹ The expression used in estimating the values given above is:

$$K_p = \frac{1}{RT} \text{ (polarization correction) } \exp \left(\frac{-18.08 r^2 \gamma}{RT} \right)$$

where

K_p = moles of gas/(cm³ melt-atm)

r is the radius of the noble gas in Angstroms

γ is the surface tension of the liquid in dyne cm⁻¹

R in the pre-exponential term = 82.0561 cm³-atm (°K)⁻¹ (g-mole)⁻¹; in the exponential term $R = 1.98717$ cal (°K)⁻¹ (g-mole)⁻¹

T is the absolute temperature in °K .

The numerical values for the radii and for the "polarization corrections" are:

	He	Kr	Xe
Radius (Angstroms)	1.22	2.0	2.18
Polarization correction	0.14	1.0	1.34

The polarization corrections were determined empirically by comparison of experimental and calculated noble gas solubilities in NaF-ZrF₄ (53-47 mole %),² NaF-KF-LiF eutectic,^{1,3} and LiF-BeF₂ (64-36 mole %).³ The surface tensions used appear in this report on page 36.

The rather large uncertainty in the gas solubilities can be rationalized from the following considerations:

- a. Experimental¹⁻³ and calculated (using the equation given in the previous paragraph) solubilities agreed to within a factor of three,
- b. Calculated solubilities depend exponentially on the assumed value of the surface tension; for the salts of this report the surface tension, in each case estimated, has a large uncertainty.

C_1	See section on Vapor Pressures, page 33.			
C_2				

All solubilities are estimated; the uncertainty is a factor of ten or greater.

Sources of Data and Methods of Estimation

Solubilities of BF_3 were assumed to be analogous to solubilities of HF. For $\text{LiF}-\text{BeF}_2-\text{ZrF}_4-\text{ThF}_4-\text{UF}_4$ (65-28-5-1-1 mole %) the measured BF_3 ¹ and HF ² solubilities both exhibited negative temperature dependence (inert-gas solubilities in fluoride melts are much smaller and show positive temperature dependence). The ratio of BF_3 to HF solubility in the range 500-800 $^{\circ}\text{C}$ for this melt was the multiple used to estimate the

BF_3 solubility in L_2B from the measured values of HF solubility.³

Solubility of HF in $\text{F}_1\text{-F}_4$ was estimated by assuming the same "free fluoride" concentration dependence as had been observed for LiF- BeF_2 mixtures.⁴ (For $\text{F}_1\text{-F}_4$, free fluoride is defined as X_{LiF} minus $(2X_{\text{BeF}_2} + 3X_{\text{MF}_4})$, where X is mole percent; for LiF- BeF_2 mixtures, free fluoride equals X_{LiF} minus $2X_{\text{BeF}_2}$). The BF_3 solubilities were then calculated by multiplying the estimated HF solubilities by the same ratios that were derived from the melt where both gas solubilities had been measured.

	700	0.30 ₄	33.3	31.46	1.1 ₉	1260

a. Calculated from the equation,

$$C_V = C_p - \frac{\alpha^2 T}{\rho \beta_T} \quad \text{where } \alpha \text{ is expansivity; } \rho, \text{ density; } \beta_T \text{ isothermal compressibility.}$$

b. Calculated from the equation,

$$\mu = \left(\frac{C_p}{C_V \beta_T \rho} \right)^{1/2} \quad \text{where } \mu \text{ is sonic velocity.}$$

c. Calculated by assuming

$$C_V = 6.R \text{ (harmonic oscillation of 2 ions) + 1.5R (free rotation of } \text{BF}_4^- \text{ ion) + Vibrational*heat capacity of } \text{BF}_4^- \text{.}$$

* Vibrational frequencies obtained from K. Nakamoto, Infrared Spectra of Inorganic and Coordination Compounds, John Wiley and Sons, N. Y., 1963, p. 106.

APPENDIX B

THERMAL DIFFUSIVITY,^a KINEMATIC VISCOSITY,^b AND PRANDTL NUMBER^c

Salt	Temp. (°C)	Therm. Diffy. (cm ² sec ⁻¹)	Kin. Visc. (cm ² sec ⁻¹)	Prandtl Number
F ₁	500	2.1 ₃ x 10 ⁻³	6.9 ₈ x 10 ⁻²	32.8
	600	2.1 ₇	3.7 ₅	17.2
	700	2.2 ₂	2.2 ₉	10.3
F ₂	500	2.3 ₅ x 10 ⁻³	7.1 ₇ x 10 ⁻²	30.4
	600	2.4 ₀	3.8 ₃	15.9
	700	2.4 ₅	2.3 ₄	9.5
F ₃	500	1.7 ₉ x 10 ⁻³	7.0 ₅ x 10 ⁻²	39.4
	600	1.8 ₂	3.7 ₃	20.5
	700	1.8 ₆	2.2 ₆	12.1
F ₄	500	1.5 ₂ x 10 ⁻³	8.9 ₂ x 10 ⁻²	58.6
	600	1.5 ₅	4.3 ₂	27.8
	700	1.5 ₈	2.4 ₄	15.4
L ₂ B	500	2.0 ₉ x 10 ⁻³	7.4 ₄ x 10 ⁻²	35.6
	600	2.1 ₄	4.3 ₆	20.4
	700	2.1 ₈	2.8 ₆	13.1
C ₁	500	1.8 ₂ x 10 ⁻³	1.0 ₂ x 10 ⁻²	5.6
	600	1.8 ₉	0.6 ₈	3.6
	700	1.9 ₇	0.5 ₀	2.5
C ₂	500	1.7 ₉ x 10 ⁻³	1.0 ₂ x 10 ⁻²	5.7
	600	1.8 ₆	0.6 ₈	3.7
	700	1.9 ₃	0.5 ₀	2.6

Calculated from the equations:

a. $X = \frac{k}{\rho C_p}$ where k is thermal conductivity; ρ , density; C_p , specific heat.

b. $\nu = \frac{\eta}{\rho}$ where η is viscosity in poise (g cm⁻¹ sec⁻¹).

c. $Pr = \frac{\nu}{X} = \frac{\eta C_p}{k}$
